## The Open Group

The Open Group is the leading vendor-neutral, international consortium for buyers and suppliers of technology. Its mission is to cause the development of a viable global information infrastructure that is ubiquitous, trusted, reliable, and as easy-to-use as the telephone. The essential functionality embedded in this infrastructure is what we term the IT DialTone. The Open Group creates an environment where all elements involved in technology development can cooperate to deliver less costly and more flexible IT solutions.

Formed in 1996 by the merger of the X/Open Company Ltd. (founded in 1984) and the Open Software Foundation (founded in 1988), The Open Group is supported by most of the world's largest user organizations, information systems vendors, and software suppliers. By combining the strengths of open systems specifications and a proven branding scheme with collaborative technology development and advanced research, The Open Group is well positioned to meet its new mission, as well as to assist user organizations, vendors, and suppliers in the development and implementation of products supporting the adoption and proliferation of systems which conform to standard specifications.
With more than 200 member companies, The Open Group helps the IT industry to advance technologically while managing the change caused by innovation. It does this by:

- Consolidating, prioritizing, and communicating customer requirements to vendors
- Conducting research and development with industry, academia, and government agencies to deliver innovation and economy through projects associated with its Research Institute
- Managing cost-effective development efforts that accelerate consistent multi-vendor deployment of technology in response to customer requirements
- Adopting, integrating, and publishing industry standard specifications that provide an essential set of blueprints for building open information systems and integrating new technology as it becomes available
- Licensing and promoting the Open Brand, represented by the " X " Device, that designates vendor products which conform to Open Group Product Standards
- Promoting the benefits of the IT DialTone to customers, vendors, and the public

The Open Group operates in all phases of the open systems technology lifecycle including innovation, market adoption, product development, and proliferation. Presently, it focuses on seven strategic areas: open systems application platform development, architecture, distributed systems management, interoperability, distributed computing environment, security, and the information superhighway. The Open Group is also responsible for the management of the UNIX trademark on behalf of the industry.

## Development of Product Standards

This process includes the identification of requirements for open systems and, now, the IT DialTone, development of Technical Standards (formerly CAE and Preliminary Specifications) through an industry consensus review and adoption procedure (in parallel with formal standards work), and the development of tests and conformance criteria.

This leads to the preparation of a Product Standard which is the name used for the documentation that records the conformance requirements (and other information) to which a vendor may register a product.

The " X " Device is used by vendors to demonstrate that their products conform to the relevant Product Standard. By use of the Open Brand they guarantee, through the Open Brand Trade Mark License Agreement (TMLA), to maintain their products in conformance with the Product Standard so that the product works, will continue to work, and that any problems will be fixed by the vendor.

## Open Group Publications

The Open Group publishes a wide range of technical documentation, the main part of which is focused on development of Technical Standards and product documentation, but which also includes Guides, Snapshots, Technical Studies, Branding and Testing documentation, industry surveys, and business titles.

There are several types of specification:

## - Technical Standards (formerly CAE Specifications)

The Open Group Technical Standards form the basis for our Product Standards. These Standards are intended to be used widely within the industry for product development and procurement purposes.
Anyone developing products that implement a Technical Standard can enjoy the benefits of a single, widely supported industry standard. Where appropriate, they can demonstrate product compliance through the Open Brand. Technical Standards are published as soon as they are developed, so enabling vendors to proceed with development of conformant products without delay.

- CAE Specifications

CAE Specifications and Developers' Specifications published prior to January 1998 have the same status as Technical Standards (see above).

- Preliminary Specifications

Preliminary Specifications have usually addressed an emerging area of technology and consequently are not yet supported by multiple sources of stable conformant implementations. They are published for the purpose of validation through implementation of products. A Preliminary Specification is as stable as can be achieved, through applying The Open Group's rigorous development and review procedures.

Preliminary Specifications are analogous to the trial-use standards issued by formal standards organizations, and developers are encouraged to develop products on the basis of them. However, experience through implementation work may result in significant (possibly upwardly incompatible) changes before its progression to becoming a Technical Standard. While the intent is to progress Preliminary Specifications to corresponding Technical Standards, the ability to do so depends on consensus among Open Group members.

- Consortium and Technology Specifications

The Open Group publishes specifications on behalf of industry consortia. For example, it publishes the NMF SPIRIT procurement specifications on behalf of the Network Management Forum. It also publishes Technology Specifications relating to OSF/1, DCE, OSF/Motif, and CDE.

Technology Specifications (formerly AES Specifications) are often candidates for consensus review, and may be adopted as Technical Standards, in which case the relevant Technology Specification is superseded by a Technical Standard.
In addition, The Open Group publishes:

- Product Documentation

This includes product documentation-programmer's guides, user manuals, and so onrelating to the Pre-structured Technology Projects (PSTs), such as DCE and CDE. It also includes the Single UNIX Documentation, designed for use as common product documentation for the whole industry.

- Guides

These provide information that is useful in the evaluation, procurement, development, or management of open systems, particularly those that relate to the Technical Standards or Preliminary Specifications. The Open Group Guides are advisory, not normative, and should not be referenced for purposes of specifying or claiming conformance to a Product Standard.

- Technical Studies

Technical Studies present results of analyses performed on subjects of interest in areas relevant to The Open Group's Technical Program. They are intended to communicate the findings to the outside world so as to stimulate discussion and activity in other bodies and the industry in general.

## Versions and Issues of Specifications

As with all live documents, Technical Standards and Specifications require revision to align with new developments and associated international standards. To distinguish between revised specifications which are fully backwards compatible and those which are not:

- A new Version indicates there is no change to the definitive information contained in the previous publication of that title, but additions/extensions are included. As such, it replaces the previous publication.
- A new Issue indicates there is substantive change to the definitive information contained in the previous publication of that title, and there may also be additions/extensions. As such, both previous and new documents are maintained as current publications.

## Corrigenda

Readers should note that Corrigenda may apply to any publication. Corrigenda information is published on the World-Wide Web at http://www.opengroup.org/corrigenda.

## Ordering Information

Full catalogue and ordering information on all Open Group publications is available on the World-Wide Web at $h t t p: / / w w w . o p e n g r o u p . o r g / p u b s . ~$

## This Technical Standard

This Technical Standard is one of a set of Technical Standards (see above) defining the $X$ Window System.

This Technical Standard specifies the $X$ Protocol for X11R6.4 and subsequent releases of the $X$ Window System.

## The X Window System Registry

The X Window System Registry is a registry of certain X-related items, to help avoid conflicts and share such items. The Open Group maintains the registry as a service to users of the $X$ Window System. Requests to register items, or questions about registration, should be addressed to:
xregistry@x.org
Electronic mail is acknowledged upon receipt. Please allow up to 4 weeks for a formal response to registration and enquiries.

All registered items must have the postal address of someone responsible for the item or a reference to a document describing the item and the postal address of where to write to obtain the document.

The X Window System Technical Standards indicate that the following items are subject to registration:

- Names of non-standard character encodings
- Prefixes for private font names (which follow the FONT keyword in the BDF specification (included in the X Window System (X11R6): Fonts and Text Technical Standard))
- Transport-specific names other than those specified by The Open Group
- The FontNameRegistry component of a FontName in the XLFD specification (included in the $\mathbf{X}$ Window System (X11R6): Fonts and Text Technical Standard)
- Values of CHARSET_ENCODING, CHARSET_REGISTRY, FONT_TYPE, and FOUNDRY in the XLFD specification (included in the X Window System (X11R6): Fonts and Text Technical Standard)
- New values of AXIS_TYPES in the XLFD specification (included in the X Window System (X11R6): Fonts and Text Technical Standard), and the semantics of each
- Window manager protocols specified by the WM_PROTOCOLS property
- Device-dependent color spaces represented by the XcmsColorSpace structure
- New values of the XIC and XOC structures for the X Input Context and X Output Context
- In the Input Device Extension (XINPUT), new input classes
- In the Display Manager Control Protocol (XDMCP) Extension, values for the ManufacturerID parameter of the Manage message
- In the X Input Method (XIM) Extension, new values of XIM_ENCODING_NEGOTIATION; also, opcodes and packet names for additions to this extension
- The organization component of names of algorithms in the Low Bandwidth Extension (LBX)
- The names of system counters, as described in the Synchronization (XSYNC) Extension

## Trademarks

Motif ${ }^{\circledR}$, OSF $/ 1^{\circledR}$, UNIX ${ }^{\circledR}$, and the " X Device ${ }^{,{ }^{\circledR}}$ are registered trademarks and IT DialTone ${ }^{\mathrm{TM}}$ and The Open Group ${ }^{\mathrm{TM}}$ are trademarks of The Open Group in the U.S. and other countries.
X Window System ${ }^{\text {TM }}$ is a trademark of The Open Group.

The Open Group gratefully acknowledges the following Working Group members for their valuable contribution to the development of this Technical Standard:

Art Barstow
Brian Bobryk
Linda Cain
Peter Daifuku
Vic Goddard
Cathy Hughes
Kaleb S. Keithley
Finnbarr P. Murphy
Spike
Steve Swales
Jeff Walls

## Referenced Documents

The following documents are referenced in this Technical Standard:

- ISO 2022: 1986, Information Processing - ISO 7-bit and 8-bit Coded Character Sets - Coded Extension Techniques.
- ISO 8859-1: 1987, Information Processing - 8-bit Single-byte Coded Graphic Character Sets - Part 1: Latin Alphabet No. 1.
- ISO/IEC 9899: 1990, Programming Languages - C, including: Amendment 1:1995 (E), C Integrity (Multibyte Support Extensions (MSE) for ISO C).
- ISO/IEC 9945-1:1996, Information Technology - Portable Operating System Interface (POSIX) - Part 1: System Application Program Interface (API) [C Language] (identical to ANSI/IEEE Std 1003.1-1996). Incorporating ANSI/IEEE Stds 1003.1-1990, 1003.1b-1993, 1003.1c-1995 and 1003.1i-1995.
- Technical Standard, estimated late 1999, X Window System (X11R6): C-Language Library (Xlib) (C904), published by The Open Group.
- Technical Standard, estimated early 2000, X Window System (X11R6): Extensions (C906), published by The Open Group.
- Technical Standard, estimated early 2000, X Window System (X11R6): Fonts and Text (C907), published by The Open Group.
- Technical Standard, estimated late 1999, X Window System (X11R6): Toolkit (C905), published by The Open Group.

### 1.1 This Issue (X11R6)

## Technical Differences

Major differences from the previous issue of this Technical Standard are as follows:

- Keysyms are provided in Appendix A for the Thai (13), Korean (14), ISO Latin-5 (15), ISO Latin-6 (16), ISO Latin-7 (17), ISO Latin-8 (18), ISO Latin-9 (19), and Currency (254) character sets.
- In Section 2.5 on page 15 and Section 5.4 on page 101, the server can now return a response to the client indicating that further authentication is required. The success field is a tri-state field with the values Failed, Success, or Authenticate.
- A code point for the euro currency has been added.

## Editorial Changes

Other changes are organizational and editorial and are not intended to suggest substantive changes. For example, events are now presented in alphabetical order, as requests always have been. The ButtonPress, ButtonRelease, KeyPress, KeyRelease, and MotionNotify events are presented in three entries instead of in a single entry.

### 1.2 Terminology

The following terms are used in this document:
can
Describes a permissible optional feature or behavior available to the user or application. The feature or behavior is mandatory for an implementation that conforms to this document. An application can rely on the existence of the feature or behavior.
implementation-dependent
(Same meaning as implementation-defined.) Describes a value or behavior that is not defined by this document but is selected by an implementor. The value or behavior may vary among implementations that conform to this document. An application should not rely on the existence of the value or behavior. An application that relies on such a value or behavior cannot be assured to be portable across conforming implementations.

The implementor shall document such a value or behavior so that it is used correctly by an application.

## legacy

Describes a feature or behavior that is being retained for compatibility with older applications, but which has limitations which make it inappropriate for developing portable applications. New applications should use alternative means of obtaining equivalent functionality.

## may

Describes a feature or behavior that is optional for an implementation that conforms to this document. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

To avoid ambiguity, the opposite of may is expressed as need not, instead of may not.
must
Describes a feature or behavior that is mandatory for an application or user. An implementation that conforms to this document shall support this feature or behavior.
shall
Describes a feature or behavior that is mandatory for an implementation that conforms to this document. An application can rely on the existence of the feature or behavior.

## should

For an implementation that conforms to this document, describes a feature or behavior that is recommended but not mandatory. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.

For an application, describes a feature or behavior that is recommended programming practice for optimum portability.

## undefined

Describes the nature of a value or behavior not defined by this document which results from use of an invalid program construct or invalid data input.
The value or behavior may vary among implementations that conform to this document. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

## unspecified

Describes the nature of a value or behavior not specified by this document which results from use of a valid program construct or valid data input.

The value or behavior may vary among implementations that conform to this document. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.
will
Same meaning as shall; shall is the preferred term.

### 1.3 Syntactic Conventions

This Technical Standard uses the following syntactic conventions.

- The syntax $\{\ldots\}$ encloses a set of alternatives.
- The syntax [...] encloses a set of structure components.
- Types are in uppercase, such as BITMASK.
- Parameter names are in italic lowercase, such as length. Alternative values appear in italics and mixed case, such as AsyncPointer. (Italics is not used in the protocol encoding.)
- Errors are in uppercase, enclosed in square brackets; for example, [ERROR].

### 1.3.1 Protocol Descriptions

Requests are described in the following format:

## RequestName

$$
\begin{aligned}
& \text { arg1: type1 } \\
& \ldots \\
& \quad \operatorname{argN}: \text { typeN } \\
& \rightarrow \\
& \text { result1: type1 } \\
& \quad . . \\
& \text { resultM: typeM } \\
& \text { Errors: kind1, ..., kindK }
\end{aligned}
$$

If no $\rightarrow$ is present in the description, then the request has no reply (it is asynchronous), although errors may still be reported. If $\rightarrow+$ is used, then one or more replies can be generated for a single request.

### 1.3.2 Events

Events are described in the following format:

## EventName

value1: type1
...
valueN: typeN

### 1.3.3 Protocol Encoding

The protocol encodings use the following syntactic conventions:

- All numbers are in decimal, unless prefixed with \#0x, in which case they are in hexadecimal (base 16).
- The syntax used to describe requests, replies, errors, events, and compound types is:

> NameofThing encode-form ... encode-form

Each encode-form describes a single component.

- For components described in the protocol as:

## name: TYPE

the encode-form is:
N TYPE name

N is the number of bytes occupied in the data stream, and TYPE is the interpretation of those bytes. For example,
depth: CARD8
becomes:
1 CARD8 depth

- For components with a static numeric value the encode-form is:

N value name
The value is always interpreted as an N-byte unsigned integer. For example, the first two bytes of a Window error are always 0 (indicating an error in general) and 3 (indicating the Window error in particular):

| 1 | 0 | Error |
| :--- | :--- | :--- |
| 1 | 3 | code |

- For components described in the protocol as:
name: $\{$ Name1, ..., NameN $\}$
the encode-form is:

| N |  | name |
| :--- | :--- | :--- |
|  | value1 | Name1 |
| $\ldots$ |  |  |
|  | valueN | NameN |

The value is always interpreted as an N -byte unsigned integer. The size of N is sometimes larger than that strictly required to encode the values. For example:
class: \{InputOutput, InputOnly, CopyFromParent \}
becomes:
2

> class
> CopyFromParent
> InputOutput
> InputOnly

- For components described in the protocol as:

NAME: TYPE or Alternative1 ...or AlternativeN
the encode-form is:

| N | TYPE | NAME |
| :--- | :--- | :--- |
|  | value1 | Alternative1 |
|  | $\ldots$ |  |
|  | valueN | AlternativeN |

The alternative values are guaranteed not to conflict with the encoding of TYPE. For example:
destination: WINDOW or PointerWindow or InputFocus
becomes:

| 4 | WINDOW | destination |
| :--- | :--- | :--- |
| 0 | PointerWindow |  |
| 1 | InputFocus |  |

- For components described in the protocol as:
value-mask: BITMASK
the encode-form is:

| N | BITMASK <br>  <br>  <br>  <br>  <br> mask1 | value-mask <br> mask-name1 |
| :---: | :--- | :--- |
|  | maskI | mask-nameN |

The individual bits in the mask are specified and named, and N is 2 or 4 . The most-significant bit in a BITMASK is reserved for use in defining chained (multi-word) bitmasks, as extensions augment existing core requests. The precise interpretation of this bit is unspecified, although a probable mechanism is that a 1 -bit indicates that another N bytes of bitmask follows, with bits within the overall mask still interpreted from least-significant to most-significant with an N -byte unit, with N -byte units interpreted in stream order, and with the overall mask being byte-swapped in individual N -byte units.

- For LISTofVALUE encodings, the request is followed by a section of the form:

```
VALUE
    encode-form
    encode-form
```

listing an encode-form for each VALUE. The NAME in each encode-form keys to the corresponding BITMASK bit. The encoding of a VALUE always occupies 4 bytes, but the number of bytes specified in the encoding-form indicates how many of the least-significant bytes are actually used; the remaining bytes are unused and their values do not matter.
In various cases, the number of bytes occupied by a component is specified by a lowercase single-letter variable name instead of a specific numeric value, and often some other component has its value specified as a simple numeric expression involving these variables. Components specified with such expressions are always interpreted as unsigned integers. The scope of such variables is always just the enclosing request, reply, error, event, or compound type structure. For example:

| 2 | $3+n$ | request length |
| :--- | :--- | :--- |
| $4 n$ | LISTofPOINT | points |

- For unused bytes (the values of the bytes are unspecified and do not matter), the encodeform is:

```
N unused
```

If the number of unused bytes is variable, the encode-form is:
$p \quad$ unused, $p=\operatorname{pad}(E)$
where $E$ is some expression, and $\operatorname{pad}(E)$ is the number of bytes needed to round $E$ up to a multiple of 4:

$$
\operatorname{pad}(E)=(4-(E \bmod 4)) \bmod 4
$$

Clients and servers use some form of reliable communication to exchange information. When the client and the server reside on different machines, a reliable duplex byte stream is required. The X protocol specifies a byte-ordering (see Section 2.5).

### 2.1 Data Formats

Clients send requests to servers. Servers respond by sending replies or errors to the client. A server can also send an event to the client asynchronously to any request. A client request can specify whether the client wishes to receive certain types of event.

Unused bytes in any data item are not guaranteed to be 0 .

### 2.1.1 Request Format

Every request contains an 8-bit major opcode and a 16-bit length field expressed in units of 4 bytes. Every request consists of 4 bytes of a header (containing the major opcode, the length field, and a data byte) followed by 0 or more additional bytes of data. The length field defines the total length of the request, including the header. The length field in a request must equal the minimum length required to contain the request. If the specified length is smaller or larger than the required length, an error is generated.
Major opcodes 128 through 255 are reserved for extensions. Extensions are intended to contain multiple requests, so extension requests typically have an additional minor opcode encoded in the "spare" data byte in the request header. However, the placement and interpretation of this minor opcode and of all other fields in extension requests are not defined by the core X protocol.

Every request on a given connection is implicitly assigned a sequence number, starting with one, that is used in replies, errors, and events.

### 2.1.2 Reply Format

Every reply contains a 32-bit length field expressed in units of 4 bytes. Every reply consists of 32 bytes followed by 0 or more additional bytes of data, as specified in the length field. Every reply also contains the least-significant 16 bits of the sequence number of the corresponding request.

### 2.1.3 Error Format

Error reports are 32 bytes long. Every error includes an 8-bit error code. Error codes 128 through 255 are reserved for extensions. Every error also includes the major and minor opcodes of the failed request and the least-significant 16 bits of the sequence number of the request. For more details, see Section 2.7.

### 2.1.4 Event Format

Events are 32 bytes long. Every event contains an 8-bit type code. The most-significant bit in this code is set if the event was generated from a SendEvent request (see SendEvent on page 73). Event codes 64 through 127 are reserved for extensions, although the core protocol does not define a mechanism for selecting interest in such events.

Every core event except KeymapNotify (see KeymapNotify on page 88) also contains the leastsignificant 16 bits of the sequence number of the last request issued by the client that was (or is currently being) processed by the server.

### 2.2 Types

The $X$ protocol uses the data types described below. The protocol encoding for each type, and additional information related to transmission of the type, is defined in Section 5.1 on page 95.

| Name | Value |
| :---: | :---: |
| LISTofTYPE | A type name of the form LISTofTYPE means a counted list of elements of the type TYPE. A separate field may be provided to indicate the number of elements (and the data type of this field is specified separately), or there may be a predefined number of elements. Except where explicitly noted, zero-length lists are legal. |
| SETofTYPE | A set indicates the presence or absence of each valid value of the data type TYPE. |
| BITMASK <br> LISTofVALUE | Various requests contain parameters of the form: <br> value-mask: BITMASK <br> value-list: LISTofVALUE |
|  | These let the client specify a subset of a heterogeneous collection of optional parameters. The value-mask specifies which parameters are to be provided; each such parameter is assigned a unique bit position. The representation of the BITMASK typically contains more bits than there are defined parameters. The unused bits in value-mask must be 0 (or the server generates a [VALUE] error). The value-list contains one value for each bit set to 1 in the mask, from least-significant to most-significant bit in the mask. Each value is represented with 4 bytes, but the actual value occupies only the least-significant bytes as required. The values of the unused bytes do not matter. |
| OR | A type of the form "T1 or $\ldots$ or $\mathrm{T} n$ " means the union of the indicated types. A single-element type is given as the element without enclosing braces. |
| WINDOW | 32-bit value (top three bits guaranteed to be 0) |
| PIXMAP | 32-bit value (top three bits guaranteed to be 0) |
| CURSOR | 32 -bit value (top three bits guaranteed to be 0) |
| FONT | 32 -bit value (top three bits guaranteed to be 0 ) |
| GCONTEXT | 32 -bit value (top three bits guaranteed to be 0) |
| COLORMAP | 32-bit value (top three bits guaranteed to be 0) |
| DRAWABLE | WINDOW or PIXMAP |
| FONTABLE | FONT or GCONTEXT |
| ATOM | 32-bit value (top three bits guaranteed to be 0) |
| VISUALID | 32-bit value (top three bits guaranteed to be 0) |
| VALUE | 32-bit quantity (used only in LISTofVALUE) |
| BYTE | 8-bit value |
| INT8 | 8-bit signed integer |
| INT16 | 16-bit signed integer |
| INT32 | 32-bit signed integer |
| CARD8 | 8-bit unsigned integer |

| Name | Value |
| :---: | :---: |
| CARD16 | 16-bit unsigned integer |
| CARD32 | 32-bit unsigned integer |
| TEXTITEM8 | TEXTELT8 or FONT |
| TEXTELT8 | [delta: INT8 string: STRING8] |
| TEXTITEM16 | TEXTELT16 or FONT |
| TEXTELT16 | [delta: INT8 |
|  | string: STRING16] |
| TIMESTAMP | CARD32 |
| COLORITEM | [pixel: CARD32 |
|  | do-red, do-green, do-blue: BOOL |
|  | red, green, blue: CARD16] |
| BITGRAVITY | \{Forget, Static, NorthWest, North, NorthEast, West, Center, East, SouthWest, South, SouthEast\} |
| WINGRAVITY | \{Unmap, Static , NorthWest, North, NorthEast, West, Center, East, SouthWest,South, SouthEast \} |
| BOOL | \{True, False\} |
| EVENT | \{KeyPress, KeyRelease, OwnerGrabButton, ButtonPress, ButtonRelease, EnterWindow, LeaveWindow, PointerMotion, PointerMotionHint, Button1Motion, Button2Motion, Button3Motion, Button4Motion, Button5Motion, ButtonMotion, Expose, VisibilityChange, StructureNotify, ResizeRedirect, SubstructureNotify, SubstructureRedirect, FocusChange, PropertyChange, ColormapChange, KeymapState\} |
| POINTEREVENT | \{ButtonPress, ButtonRelease, EnterWindow, LeaveWindow, <br> PointerMotion, PointerMotionHint, Button1Motion, <br> Button2Motion, Button3Motion, Button4Motion, Button5Motion, <br> ButtonMotion, KeymapState\} |
| DEVICEEVENT | \{KeyPress, KeyRelease, ButtonPress, ButtonRelease, PointerMotion, Button1Motion, Button2Motion, Button3Motion, Button4Motion, Button5Motion, ButtonMotion $\}$ |
| KEYSYM | 32 -bit value (top three bits guaranteed to be 0 ) |
| KEYCODE | CARD8 |
| BUTTON | CARD8 |
| KEYMASK | \{Shift, Lock, Control, Mod1, Mod2, Mod3, Mod4, Mod5\} |
| BUTMASK | \{Button1, Button2, Button3, Button4, Button5\} |
| KEYBUTMASK | KEYMASK or BUTMASK |
| STRING8 | LISTofCARD8 |
| STRING16 | LISTofCHAR2B |
| CHAR2B | [byte1, byte2: CARD8] |
| POINT | [ $x, y$ : INT16] |
| RECTANGLE | $[x, y:$ INT16, width, height: CARD16] |
| ARC | $[x, y$ : INT16, width, height: CARD16, angle1, angle2: INT16] |

| Name | Value |
| :--- | :--- |
| HOST | [family: Internet, Chaos \} <br> address: LISTofBYTE] |

The $[x, y]$ coordinates of a RECTANGLE specify the upper-left corner.
Characters in a STRING16 comprise two bytes that can index into a 2-D matrix; ${ }^{1}$ hence, the use of CHAR2B rather than CARD16. The server never byte-swaps CHAR2B quantities.

Fonts should be defined with 2-byte matrix indexing. For fonts constructed with linear indexing, a CHAR2B can be interpreted as a 16-bit number by treating byte1 as the most-significant byte. Clients should always transmit byte1 first.

The length, format, and interpretation of a HOST address are specific to the family (see ChangeHosts on page 29).

[^0]
### 2.3 Atoms

Conceptually, atoms are unique names that clients can use to interchange information efficiently. They can be thought of as strings without an encoding. The core $X$ protocol imposes no semantics on these names. Other Technical Standards may specify semantics for them.
A client uses the InternAtom protocol request to register a byte sequence with the server. The server returns a 32-bit value (with the top three bits 0 ) that uniquely represents the byte sequence. The inverse operator is GetAtomName.

## Predefined Atoms

A predefined atom is an atom that any server recognizes without the client having to intern it. The core $X$ protocol specifies that certain atoms are predefined. For a list of predefined atoms, see Section 5.3 on page 100.
Predefinition is an optimization to eliminate routine InternAtom requests from the start-up phase of many client applications. Applications can use any predefined atom as though it had issued an InternAtom request successfully.

Predefined atoms are predefined only in the sense of having numeric values, not in the sense of having required semantics.
Language interfaces should incorporate information on which atoms are predefined, to avoid unnecessary InternAtom requests, but these interfaces should make no distinction to their callers between predefined atoms and other atoms. For example, an implementation might maintain a single symbol or atom cache, initializing it with the predefined atoms.

### 2.4 Input Devices

### 2.4.1 KEYCODE and KEYSYM

A KEYCODE represents a physical or logical key on an input device. KEYCODE values are in the range from 8 up to and including 255. The numeric value of a KEYCODE provides no intrinsic information to the application. The mapping between keys and KEYCODEs cannot be changed using the $X$ protocol.
A KEYSYM is an encoding of a symbol on the cap of a key. The set of defined KEYSYMs include several common character sets as well as a set of common keyboard symbols. KEYSYMs are specified in Appendix A on page 163.
A list of KEYSYMs is associated with each KEYCODE. The list is intended to convey the set of symbols on the corresponding key. If the list (ignoring trailing NoSymbol entries) is a single KEYSYM " $K$ ", then the list is treated as if it were the list " $K$ NoSymbol $K$ NoSymbol". If the list (ignoring trailing NoSymbol entries) is a pair of KEYSYMs "K1 K2", then the list is treated as if it were the list "K1 K2 K1 K2". If the list (ignoring trailing NoSymbol entries) is a triple of KEYSYMs "K1 K2 K3", then the list is treated as if it were the list "K1 K2 K3 NoSymbol". When an explicit "void" element is desired in the list, the value VoidSymbol can be used.

The first 4 elements of the list are split into two groups of KEYSYMs. Group 1 contains the first and second KEYSYMs; Group 2 contains the third and fourth KEYSYMs. Within each group, if the second element of the group is NoSymbol, then the group should be treated as if the second element were the same as the first element, except when the first element is an alphabetic KEYSYM " $K$ " for which both lowercase and uppercase forms are defined. In that case, the group should be treated as if the first element were the lowercase form of " $K$ " and the second element were the uppercase form of " $K$ ".

The rules for obtaining a KEYSYM from a KeyPress event make use of only the Group 1 and Group 2 KEYSYMs; no interpretation of other KEYSYMs in the list is defined. The modifier state determines which group to use. Switching between groups is controlled by the KEYSYM named MODE SWITCH, by attaching that KEYSYM to some KEYCODE and attaching that KEYCODE to any one of the modifiers Mod1 through Mod5. This modifier is called the group modifier. For any KEYCODE, Group 1 is used when the group modifier is off, and Group 2 is used when the group modifier is on.

### 2.4.2 Lock Modifier

The Lock modifier is interpreted as CapsLock when the KEYSYM named CAPS LOCK is attached to some KEYCODE and that KEYCODE is attached to the Lock modifier. The Lock modifier is interpreted as ShiftLock when the KEYSYM named SHIFT LOCK is attached to some KEYCODE and that KEYCODE is attached to the Lock modifier. If the Lock modifier could be interpreted as both CapsLock and ShiftLock, the CapsLock interpretation is used.

The operation of keypad keys is controlled by the KEYSYM named NUM LOCK, by attaching that KEYSYM to some KEYCODE and attaching that KEYCODE to any one of the modifiers Mod1 through Mod5. This modifier is called the numlock modifier. The standard KEYSYMs with the prefix KEYPAD in their name are called keypad KEYSYMs; these are KEYSYMs with numeric value in the hexadecimal range \#0xFF80 to \#0xFFBD inclusive. In addition, implementationdependent KEYSYMs in the hexadecimal range \#0x11000000 to \#0x1100FFFF are also keypad KEYSYMs.

Within a group, the choice of KEYSYM is determined by applying the first rule that is satisfied from the following list:

- The numlock modifier is on and the second KEYSYM is a keypad KEYSYM. In this case, if the Shift modifier is on, or if the Lock modifier is on and is interpreted as ShiftLock, then the first KEYSYM is used; otherwise, the second KEYSYM is used.
- The Shift and Lock modifiers are both off. In this case, the first KEYSYM is used.
- The Shift modifier is off, and the Lock modifier is on and is interpreted as CapsLock. In this case, the first KEYSYM is used, but if that KEYSYM is lowercase alphabetic, then the corresponding uppercase KEYSYM is used instead.
- The Shift modifier is on, and the Lock modifier is on and is interpreted as CapsLock. In this case, the second KEYSYM is used, but if that KEYSYM is lowercase alphabetic, then the corresponding uppercase KEYSYM is used instead.
- The Shift modifier is on, or the Lock modifier is on and is interpreted as ShiftLock, or both. In this case, the second KEYSYM is used.

The mapping between KEYCODEs and KEYSYMs is not used directly by the server; it is merely stored for reading and writing by clients.

### 2.4.3 Pointers

Buttons are always numbered starting with 1 .

### 2.5 Connection Setup

### 2.5.1 Connection Initiation

The client sends an initial byte of data to identify the byte order to be employed. The value of the byte is $\# 0 \times 42$ or $\# 0 \times 6 c$. The value $\# 0 \times 42$ (ASCII uppercase B) means values are transmitted most-significant byte first, and value \#0x6c (ASCII lowercase 1 (ell)) means values are transmitted least-significant byte first. Except where explicitly noted in the protocol, the client transmits all 16-bit and 32-bit quantities with this byte order, and the server returns all 16-bit and 32-bit quantities with this byte order.

Following the byte-order byte, the client sends the following information at connection setup:

```
protocol-major-version: CARD16
protocol-minor-version: CARD16
authorization-protocol-name: STRING8
authorization-protocol-data: STRING8
```

The version numbers indicate what version of the protocol the client expects the server to implement.
The authorization name indicates what authorization protocol the client expects the server to use, and the data is specific to that protocol. Valid authorization mechanisms are unspecified. A server that implements a different protocol than the client expects, or that only implements the host-based mechanism, may ignore this information. If both name and data strings are empty, this is to be interpreted as "no explicit authorization".

### 2.5.2 Server Response

The server sends the client the following information at connection setup:
result: \{Failed, Success, Authenticate\}
If result is Failed, the connection is not established and the server sends the client the following additional data:

```
protocol-major-version: CARD16
protocol-minor-version: CARD16
reason: STRING8
```

If result is Authenticate, the server requires further authentication negotiation, and the server sends the client the following additional data:
reason: STRING8
The contents of the reason string are specific to the authorization protocol in use. The semantics of this authentication negotiation are unspecified, except that the negotiation must eventually terminate with a reply from the server containing a result of Failed or Success.

If result is Success, the connection is established and the server sends the client the following additional data:

```
protocol-major-version: CARD16
protocol-minor-version: CARD16
vendor: STRING8
release-number: CARD32
resource-id-base, resource-id-mask: CARD32
image-byte-order: \(\{\) LSBFirst, MSBFirst \(\}\)
bitmap-scanline-unit: \(\{8,16,32\}\)
bitmap-scanline-pad: \(\{8,16,32\}\)
bitmap-bit-order: \(\{\) LSBitFirst, MSBitFirst \(\}\)
pixmap-formats: LISTofFORMAT
roots: LISTofSCREEN
motion-buffer-size: CARD32
maximum-request-length: CARD16
min-keycode, max-keycode: KEYCODE
```

where:
FORMAT: [depth: CARD8, bits-per-pixel: $\{1,4,8,16,24,32\}$ scanline-pad: $\{8,16,32\}$ ]

SCREEN: [root: WINDOW
width-in-pixels, height-in-pixels: CARD16
width-in-millimeters, height-in-millimeters: CARD16
allowed-depths: LISTofDEPTH
root-depth: CARD8
root-visual: VISUALID
default-colormap: COLORMAP
white-pixel, black-pixel: CARD32
min-installed-maps, max-installed-maps: CARD16
backing-store: $\{$ Never, WhenMapped, Always\}
save-under: BOOL
current-input-masks: SETofEVENT]
DEPTH: [depth: CARD8
visuals: LISTofVISUALTYPE]
VISUALTYPE: [visual-id: VISUALID
class:
\{StaticGray, StaticColor, TrueColor,
GrayScale, PseudoColor, DirectColor\}
red-mask, green-mask, blue-mask: CARD32
bits-per-rgb-value: CARD8
colormap-entries: CARD16]

### 2.5.3 Server Information

This section describes the information that is global to the server.
The vendor string gives some identification of the owner of the server implementation. The vendor controls the semantics of the release number.

The resource-id-mask contains a single contiguous set of bits (at least 18). The client allocates resource IDs for types WINDOW, PIXMAP, CURSOR, FONT, GCONTEXT, and COLORMAP by choosing a value with only some subset of these bits set and ORing it with resource-id-base. Only values constructed in this way can be used to name newly created resources over this connection. Resource IDs never have the top three bits set. The client is not restricted to linear or contiguous allocation of resource IDs. Once an ID has been freed, it can be reused, but this should not be necessary. An ID must be unique with respect to the IDs of all other resources, not just other resources of the same type. However, note that the value spaces of resource identifiers, atoms, visual-ids, and keysyms are distinguished by context, and as such, are not required to be disjoint; for example, a given numeric value might be both a valid window ID, a valid atom, and a valid keysym.

The server byte-swaps data to match the client, except that images are always transmitted and received in formats (including byte order) specified by the server. The byte order for images is given by image-byte-order and applies to each scanline unit in XY format (bitmap format) and to each pixel value in $Z$ format.

A bitmap is represented in scanline order. Each scanline is padded to a multiple of bitmap-scanline-pad bits. The scanline is quantized in multiples of bits as given by bitmap-scanline-unit. The bitmap-scanline-unit is always less than or equal to the bitmap-scanline-pad. Within each unit, the leftmost bit in the bitmap is either the least-significant or most-significant bit in the unit, as given by bitmap-bit-order. If a pixmap is represented in XY format, each plane is represented as a bitmap, and the planes appear from most-significant to least-significant in bit order with no padding between planes.
pixmap-formats contains one entry for each depth value. The entry describes the $Z$ format used to represent images of that depth. An entry for a depth is included if any screen supports that depth, and all screens supporting that depth must support only that Z format for that depth. In Z format, the pixels are in scanline order, left to right within a scanline. The number of bits used to hold each pixel is given by bits-per-pixel. bits-per-pixel may be larger than strictly required by the depth, in which case the least-significant bits are used to hold the pixmap data, and the values of the unused high-order bits are unspecified. When the bits-per-pixel is 4, the order of nibbles in the byte is the same as the image byte-order. When the bits-per-pixel is 1 , the format is identical for bitmap format. Each scanline is padded to a multiple of bits as given by scanlinepad. When bits-per-pixel is 1 , this is identical to bitmap-scanline-pad.
The core X protocol supports multiple screens per display. Movement of the pointer between screens is implementation-dependent and is transparent to the protocol. No geometry is defined among screens.

The server may retain the recent history of pointer motion and may do so to a finer granularity than is reported by MotionNotify events. The GetMotionEvents request makes such history available. The motion-buffer-size gives the approximate maximum number of elements in the history buffer.
maximum-request-length specifies the maximum length of a request accepted by the server, in 4byte units. That is, length is the maximum value that can appear in the length field of a request. Requests larger than this maximum generate a [LENGTH] error, and the server reads and discards the entire request. The maximum-request-length is always at least 4096 units (16384 bytes).
min-keycode and max-keycode specify the smallest and largest keycode values transmitted by the server. min-keycode is never less than 8 , and max-keycode is never greater than 255 . Not all keycodes in this range are required to have corresponding keys.

### 2.5.4 Screen Information

This section describes the information that applies per screen.
allowed-depths specifies the pixmap and window depths that are supported. Pixmaps are supported for each depth listed, and windows of that depth are supported if at least one visual type is listed for the depth. A pixmap depth of 1 is always supported and listed, but windows of depth 1 might not be supported. A depth of 0 is never listed, but zero-depth InputOnly windows are always supported.
root-depth and root-visual specify the depth and visual type of the root window. width-in-pixels and height-in-pixels specify the size of the root window (which cannot be changed). The class of the root window is always InputOutput. width-in-millimeters and height-in-millimeters can be used to determine the physical size and the aspect ratio.
default-colormap is the colormap initially associated with the root window. Clients with minimal color requirements creating windows of the same depth as the root may want to allocate from this map by default.
black-pixel and white-pixel are permanently allocated entries in the default colormap that can be used in implementing a monochrome application. The actual RGB values of black-pixel and white-pixel are unspecified.
The border of the root window is initially a pixmap filled with black-pixel. The initial background of the root window is a pixmap filled with some unspecified two-color pattern using black-pixel and white-pixel.
min-installed-maps specifies the number of maps that can be guaranteed to be installed simultaneously (with InstallColormap), regardless of the number of entries allocated in each map. max-installed-maps specifies the maximum number of maps that might possibly be installed simultaneously, depending on their allocations. Multiple static-visual colormaps with identical contents but differing in resource ID should be considered as a single map for the purposes of this number. For the case of a single hardware colormap, both values are $1 .{ }^{2}$
backing-store indicates when the server supports backing store for this screen, although it may be storage-limited in the number of windows it can support at once.

If save-under is True, the server can support the save-under mode in CreateWindow and ChangeWindowAttributes, although again it may be storage-limited.
current-input-events is what GetWindowAttributes would return for all-event-masks on the root window.

[^1]
### 2.5.5 Visual Information

This section describes the information that applies per visual type.

| PseudoColor | A pixel value indexes a colormap to produce independent RGB values; the <br> RGB values can be changed dynamically. |
| :--- | :--- |
| GrayScale | Treated in the same way as PseudoColor, except that the primary that drives <br> the screen is unspecified; thus, the client should always store the same value <br> for red, green, and blue in colormaps. |
| DirectColor | A pixel value is decomposed into separate RGB subfields, and each subfield <br> separately indexes the colormap for the corresponding value. The RGB values <br> can be changed dynamically. |
| TrueColor | Treated in the same way as DirectColor, except that the colormap has <br> predefined read-only RGB values. These values are implementation- <br> dependent, but provide linear or near-linear increasing ramps in each primary. |
| StaticColor | Treated in the same way as PseudoColor, except that the colormap has <br> predefined read-only RGB values, which are implementation-dependent. |
| StaticGray | Treated in the same way as StaticColor, except that the red, green, and blue <br> values are equal for any single pixel value, resulting in shades of gray. |
| StaticGray with a two-entry colormap can be thought of as monochrome. |  |

red-mask, green-mask, and blue-mask are only defined for DirectColor and TrueColor. Each has one contiguous set of bits set to 1 with no intersections. Usually each mask has the same number of bits set to 1 .
bits-per-rgb-value specifies the $\log _{2}$ of the number of distinct color intensity values (individually) of red, green, and blue. This number need not bear any relation to the number of colormap entries. Actual RGB values are always passed in the protocol within a 16 -bit spectrum, with 0 being minimum intensity and 65535 being the maximum intensity. On hardware that provides a linear zero-based intensity ramp, the following relationship exists:
hw-intensity $=$ protocol-intensity / (65536 / total-hw-intensities)
Colormap entries are indexed from 0 . colormap-entries defines the number of available colormap entries in a newly created colormap. For DirectColor and TrueColor, this is usually 2 to the power of the maximum number of bits set to 1 in red-mask, green-mask, and blue-mask.
A server may support a given visual type for more than one depth or for more than one screen. There may be multiple instances of a visual type at a given depth.

### 2.6 Connection Close

At connection close, all event selections made by the client are discarded. If the client has the pointer actively grabbed, an UngrabPointer is performed. If the client has the keyboard actively grabbed, an UngrabKeyboard is performed. All passive grabs by the client are released. If the client has the server grabbed, an UngrabServer is performed. All selections (see SetSelectionOwner on page 77) owned by the client are disowned. If the mode parameter of the SetCloseDownMode request (see SetCloseDownMode on page 74) is RetainPermanent or RetainTemporary, then all resources (including colormap entries) allocated by the client are marked as permanent or temporary, respectively (but this does not prevent other clients from explicitly destroying them). If mode is Destroy, all the client's resources are destroyed.
When a client's resources are destroyed, for each window in the client's save-set, if the window is an inferior of a window created by the client, the save-set window is reparented to the closest ancestor such that the save-set window is not an inferior of a window created by the client. If the save-set window is unmapped, a MapWindow request is performed on it (even if it was not an inferior of a window created by the client). The reparenting leaves unchanged the absolute coordinates (with respect to the root window) of the upper-left outer corner of the save-set window. After save-set processing, all windows created by the client are destroyed. For each non-window resource created by the client, the appropriate Free request is performed. All colors and colormap entries allocated by the client are freed.
A server goes through a cycle of having no connections and having some connections. At every transition to the state of having no connections as a result of a connection closing with a mode of Destroy, the server resets its state as if it had just been started. This starts by destroying all lingering resources from clients that have terminated with a mode of RetainPermanent or RetainTemporary. It additionally includes deleting all but the predefined atom identifiers, deleting all properties on all root windows, resetting all device maps and attributes (key click, bell volume, acceleration), resetting the access control list, restoring the standard root tiles and cursors, restoring the default font path, and restoring the input focus to state PointerRoot.
Closing a connection with a mode of RetainPermanent or RetainTemporary does not reset the server.

### 2.7 Errors

When a request terminates with an error, the request has no side effects except in the following cases:

- Partial execution may occur if the following requests fail:

| ChangeGC | PolyText16 |
| :--- | :--- |
| ChangeKeyboardControl | PolyText8 |
| ChangeWindowAttributes | StoreColors |
| FreeColors |  |

- An [ALLOC] error can occur at any time in any request.

The following error codes may be returned:
[ACCESS] The client attempted to grab a key/button combination already grabbed by another client.
The client attempted to free a colormap entry not allocated by the client, or to free an entry in a colormap that was created with all entries writable.
The client attempted to store into a read-only or an unallocated colormap entry.
An unauthorized client attempted to modify the access control list.
The client attempted to select an event type that only one client can select at a time when another client has already selected it.
[ALLOC] The server failed to allocate a resource. An [ALLOC] error can occur at any time in any request. Whether partial execution of the request occurs is undefined.
[ATOM] A value for an ATOM parameter does not name a defined atom.
[COLORMAP] A value for a COLORMAP parameter does not name a defined colormap.
[CURSOR] A value for a CURSOR parameter does not name a defined cursor.
[DRAWABLE] A value for a DRAWABLE parameter does not name a defined window or pixmap.
[FONT] A value for a FONT parameter does not name a defined font.
A value for a FONTABLE parameter does not name a defined font or a defined GContext (see QueryFont on page 69).
[GCONTEXT] A value for a GCONTEXT parameter does not name a defined graphics context.
[IDCHOICE] The value chosen for a resource identifier is not included in the range assigned to the client or is already in use.
[IMPLEMENTATION]
The server does not implement some aspect of the request. This error is not listed for any of the requests.
[LENGTH] The length of a request is not the value the server expects.
The length of a request exceeds the maximum length accepted by the server.
[MATCH] An InputOnly window is used as a drawable.

In a graphics request, the GCONTEXT parameter does not have the same root and depth as the destination DRAWABLE parameter.

A parameter (or pair of parameters) has the correct type and range, but it fails to match in some other way required by the request.
[NAME] A font or color of the specified name does not exist.
[PIXMAP] A value for a PIXMAP parameter does not name a defined pixmap.
[REQUEST] The major or minor opcode does not specify a valid request.
[VALUE] A numeric value falls outside the set of values accepted by the request.
[WINDOW] A value for a WINDOW parameter does not name a defined window.
Note: The [ATOM], [COLORMAP], [CURSOR], [DRAWABLE], [FONT], [GCONTEXT], [PIXMAP], and [WINDOW] errors are also used when the parameter type is extended by union with a set of fixed alternatives; for example, \{WINDOW or PointerRoot or None $\}$.

Additional information returned by each type of error is specified in Section 5.7 on page 158.

### 2.8 Flow Control and Concurrency

Whenever the server is writing to a given connection, the server may stop reading from that connection; but if the writing would block, it must continue to service other connections. The server is not required to buffer more than a single request per connection at one time. For a given connection to the server, a client can block while reading from the connection but should read when writing would block. Failure on the part of a client to obey this rule may result in a deadlocked connection. ${ }^{3}$

Whether or not a server is implemented with internal concurrency, the overall effect must be as if individual requests are executed to completion in some serial order, and requests from a given connection must be executed in delivery order (that is, the total execution order is a shuffle of the individual streams). The execution of a request includes validating all parameters, collecting all data for any reply, and generating and queueng all required events. However, it does not include the actual transmission of the reply and the events. In addition, the effect of any other cause that can generate multiple events (for example, activation of a grab or pointer motion) must effectively generate and queue all required events indivisibly with respect to all other causes and requests. For a request from a given client, any events destined for that client that are caused by executing the request must be sent to the client before any reply or error is sent.
3. Application Usage: Deadlock is especially likely if the transport layer has little buffering or if the client sends many requests without ever reading replies or checking for errors and events.

This chapter lists alphabetically each type of request that a client can send to a server.
This chapter follows the syntactic conventions set out in Section 1.3 on page 3.

## AllocColor

cmap: COLORMAP
red, green, blue: CARD16
$\rightarrow$
pixel: CARD32
red, green, blue: CARD16
Errors: [ALLOC], [COLORMAP]
This request allocates a read-only colormap entry corresponding to the closest RGB values provided by the hardware. It also returns the pixel and the RGB values actually used. Multiple clients requesting the same effective RGB values can be assigned the same read-only entry, allowing entries to be shared.

## AllocColorCells

```
    cmap: COLORMAP
    colors, planes: CARD16
    contiguous: BOOL
->
    pixels, masks: LISTofCARD32
```

## Errors: [ALLOC], [COLORMAP], [VALUE]

colors must be positive and planes must be non-negative, or a [VALUE] error results. If C colors and P planes are requested, then C pixels and P masks are returned. No mask has any bits in common with any other mask or with any of the pixels. By ORing together masks and pixels, $C * 2^{P}$ distinct pixels can be produced; all are allocated writable by the request. For GrayScale or PseudoColor, each mask has exactly one bit set to 1 ; for DirectColor, each mask has exactly three bits set to 1 . If contiguous is True and if all masks are ORed together, a single contiguous set of bits is formed for GrayScale or PseudoColor, and three contiguous sets of bits (one within each pixel subfield) for DirectColor. The RGB values of the allocated entries are unspecified.

## AllocColorPlanes

cmap: COLORMAP<br>colors, reds, greens, blues: CARD16<br>contiguous: BOOL<br>$\rightarrow$<br>pixels: LISTofCARD32<br>red-mask, green-mask, blue-mask: CARD32

Errors: [ALLOC], [COLORMAP], [VALUE]
colors must be positive and reds, greens, and blues must be non-negative, or a [VALUE] error results. If C colors, R reds, G greens, and B blues are requested, then C pixels are returned, and the masks have R, G, and B bits set, respectively. If contiguous is True, then each mask has a contiguous set of bits. No mask has any bits in common with any other mask or with any of the pixels. For DirectColor, each mask lies within the corresponding pixel subfield. By ORing together subsets of masks with pixels, $C * 2^{R+G+B}$ distinct pixels can be produced; all of these are allocated writable by the request. The initial RGB values of the allocated entries are unspecified. In the colormap, there are only $C * 2^{R}$ independent red entries, $C * 2{ }^{G}$ independent green entries, and $C * 2^{B}$ independent blue entries. This is true even for PseudoColor. When the colormap entry for a pixel value is changed using StoreColors or StoreNamedColor, the pixel is decomposed according to the masks and the corresponding independent entries are updated.

## AllocNamedColor

```
    cmap: COLORMAP
    name:STRING8
->
    pixel: CARD32
    exact-red, exact-green, exact-blue: CARD16
    visual-red,visual-green,visual-blue: CARD16
    Errors: [ALLOC], [COLORMAP], [NAME]
```

This request looks up the named color with respect to the screen associated with cmap. Then it does an AllocColor on cmap. The exact RGB values specify the true values for the color, and the visual values specify the values actually used in the colormap. name is compared, caseinsensitively, against valid color names. If name does not use the ISO Latin- 1 encoding, the results are implementation-dependent.

## AllowEvents

mode: \{AsyncPointer, SyncPointer, ReplayPointer, AsyncKeyboard, SyncKeyboard, ReplayKeyboard, AsyncBoth, SyncBoth\} time: TIMESTAMP or CurrentTime

## Errors: [VALUE]

This request releases some queued events if the client has caused a device to freeze. The request has no effect if time is earlier than the last-grab time of the most recent active grab for the client or later than the current server time.
The following effects are specific to values of mode:
AsyncPointer If the pointer is frozen by the client, pointer event processing continues normally. If the pointer is frozen twice by the client on behalf of two separate grabs, the request thaws for both. The request has no effect if the pointer is not frozen by the client, but the pointer need not be grabbed by
the client.

SyncPointer | If the pointer is frozen and actively grabbed by the client, pointer event |
| :--- |
| processing continues normally until the next ButtonPress or ButtonRelease |
| event is reported to the client, at which time the pointer again appears to |
| freeze. However, if the reported event causes the pointer grab to be |
| released, then the pointer does not freeze. The request has no effect if the |
| pointer is not frozen by the client or if the pointer is not grabbed by the |
| client. |
| If the pointer is actively grabbed by the client and is frozen as the result of |
| an event having been sent to the client (either from the activation of a |
| GrabButton or from a previous AllowEvents with mode SyncPointer but not |
| from a GrabPointer), then the pointer grab is released and that event is |
| completely reprocessed, this time ignoring any passive grabs at or above |
| (towards the root) the grab-window of the grab just released. The request |
| has no effect if the pointer is not grabbed by the client or if the pointer is |
| not frozen as the result of an event. |
| If the keyboard is frozen by the client, keyboard event processing |
| continues normally. If the keyboard is frozen twice by the client on behalf |
| of two separate grabs, the request thaws for both. The request has no |
| effect if the keyboard is not frozen by the client, but the keyboard need |
| not be grabbed by the client. |

| If the keyboard is frozen and actively grabbed by the client, keyboard |
| :--- |
| event processing continues normally until the next KeyPress or KeyRelease |

event is reported to the client, at which time the keyboard again appears
to freeze. However, if the reported event causes the keyboard grab to be
released, then the keyboard does not freeze. The request has no effect if
the keyboard is not frozen by the client or if the keyboard is not grabbed
by the client.
client on behalf of two separate grabs, the request thaws for both. The request has no effect unless both pointer and keyboard are frozen by the client.

AsyncPointer, SyncPointer, and ReplayPointer have no effect on processing of keyboard events. AsyncKeyboard, SyncKeyboard, and ReplayKeyboard have no effect on processing of pointer events.
It is possible for both a pointer grab and a keyboard grab to be active simultaneously (by the same or different clients). When a device is frozen on behalf of either grab, no event processing is performed for the device. It is possible for a single device to be frozen because of both grabs. In this case, the freeze must be released on behalf of both grabs before events can again be processed. If a device is frozen twice by a single client, then a single AllowEvents releases both.

## Bell

percent: INT8

## Errors: [VALUE]

This request rings the bell at a volume relative to the base volume, if possible. percent can range from -100 to 100 inclusive, or a [VALUE] error results.
Values from -100 up to and including 0 specify a volume that varies linearly from silence ( -100 ) to the base volume (0):

$$
\text { base }+\left[\left(\text { base }{ }^{*} \text { percent }\right) / 100\right]
$$

Values from 0 up to and including 100 specify a volume that varies linearly from the base volume (0) up to the maximum volume (100):

$$
\text { base }-[(\text { base* percent }) / 100]+\text { percent }
$$

## ChangeActivePointerGrab

event-mask: SETofPOINTEREVENT
cursor: CURSOR or None
time: TIMESTAMP or CurrentTime
Errors: [CURSOR], [VALUE]
This request changes the specified dynamic parameters if the pointer is actively grabbed by the client and time is no earlier than the last-pointer-grab time and no later than the current server time. The interpretation of event-mask and cursor are the same as in GrabPointer. This request has no effect on the parameters of any passive grabs established with GrabButton.

## ChangeGC

## $g c:$ GCONTEXT

value-mask: BITMASK
value-list: LISTofVALUE
Errors: [ALLOC], [FONT], [GCONTEXT], [MATCH], [PIXMAP], [VALUE]
This request changes components in gc. value-mask and value-list specify which components are to be changed. The values and restrictions are the same as for CreateGC.
Changing the clip-mask also overrides any previous SetClipRectangles request on the context. Changing dash-offset or dashes overrides any previous SetDashes request on the context.

The order in which components are verified and altered is implementation-dependent. If an error is generated, a subset of the components may have been altered.

## ChangeHosts

```
    mode: {Insert, Delete}
```

host: HOST

## Errors: [ACCESS], [VALUE]

This request adds host to, or removes it from, the access control list. When the access control mechanism is enabled and a host not in the list tries to establish a connection to the server, the server refuses the connection.
The client must have been granted permission by a implementation-dependent method to execute this request, or an [ACCESS] error results.
The following address families are defined:

- For the Internet family, IPv4 addresses are 4 bytes long. The address bytes are in standard IP order.
- For the Chaos family, the address is 2 bytes long.

A server is not required to support these families and may support families not listed here. Use of an unsupported family, an improper address format, or an improper address length within a supported family results in a [VALUE] error.

## ChangeKeyboardControl

value-mask: BITMASK
value-list: LISTofVALUE

## Errors: [MATCH], [VALUE]

This request controls various aspects of the keyboard. value-mask and value-list specify which controls are to be changed. The possible values are:

| Control | Type |
| :--- | :--- |
| key-click-percent | INT8 |
| bell-percent | INT8 |
| bell-pitch | INT16 |
| bell-duration | INT16 |
| led | CARD8 |
| led-mode | \{On,Off $\}$ |
| key | KEYCODE |
| auto-repeat-mode | $\{$ On,Off,Default $\}$ |

key-click-percent sets the volume for key clicks between 0 (off) and 100 (loud) inclusive, if possible. Setting to -1 restores the implementation-dependent default. Other negative values generate a [VALUE] error.
bell-percent sets the base volume for the bell between 0 (off) and 100 (loud) inclusive, if possible. Setting to -1 restores the implementation-dependent default. Other negative values generate a [VALUE] error.
bell-pitch sets the pitch (specified in Hz) of the bell, if possible. Setting to -1 restores the implementation-dependent default. Other negative values generate a [VALUE] error.
bell-duration sets the duration of the bell (specified in milliseconds), if possible. Setting to -1 restores the implementation-dependent default. Other negative values generate a [VALUE] error.

If both led-mode and led are specified, then the state of that LED is changed, if possible. If only led-mode is specified, then the state of all LEDs is changed, if possible. At most 32 LEDs, numbered from one, are supported. No standard interpretation of LEDs is defined. It is a [MATCH] error if led is specified without led-mode.

If both auto-repeat-mode and key are specified, then the auto-repeat mode of that key is changed, if possible. If only auto-repeat-mode is specified, then the global auto-repeat mode for the entire keyboard is changed, if possible, without affecting the per-key settings. It is a [MATCH] error if key is specified without auto-repeat-mode. Each key has an individual mode of whether or not it should auto-repeat and a default setting for that mode. In addition, there is a global mode of whether auto-repeat should be enabled or not and a default setting for that mode. When the global mode is On, keys should obey their individual auto-repeat modes. When the global mode is Off, no keys should auto-repeat. An auto-repeating key generates alternating KeyPress and KeyRelease events. When a key is used as a modifier, it is desirable for the key not to auto-repeat, regardless of the auto-repeat setting for that key.

A bell generator connected with the console but not directly on the keyboard is treated as if it were part of the keyboard.

The order in which controls are verified and altered is implementation-dependent. If an error is generated, a subset of the controls may have been altered.

## ChangeKeyboardMapping

first-keycode: KEYCODE
keysyms-per-keycode: CARD8
keysyms: LISTofKEYSYM
Errors: [ALLOC], [VALUE]
This request defines the symbols for the specified number of keycodes, starting with first-keycode. The symbols for keycodes outside this range remained unchanged. The number of elements in the keysyms list must be a multiple of keysyms-per-keycode, or a [LENGTH] error results. firstkeycode must be greater than or equal to min-keycode as returned in the connection setup, or a [VALUE] error results; and:

$$
\text { first-keycode }+ \text { (keysyms-length/keysyms-per-keycode) }-1
$$

must be less than or equal to max-keycode as returned in the connection setup, or a [VALUE] error results. KEYSYM number N (counting from 0 ) for keycode K has an index (counting from 0 ) of:

$$
(\mathrm{K}-\text { first-keycode })^{*} \text { keysyms-per-keycode }+\mathrm{N}
$$

in keysyms. The client can arbitrarily choose keysyms-per-keycode to be large enough to hold all desired symbols. A special KEYSYM value of NoSymbol should be used to fill in unused elements for individual keycodes. It is valid for NoSymbol to appear in non-trailing positions of the effective list for a keycode.

This request generates a MappingNotify event.
There is no requirement that the server interpret this mapping; it is merely stored for reading and writing by clients (see Section 2.4).

## ChangePointerControl

do-acceleration, do-threshold: BOOL
acceleration-numerator, acceleration-denominator: INT16
threshold: INT16
Errors: [VALUE]
This request defines how the pointer moves. The acceleration is a multiplier for movement expressed as a fraction. For example, specifying $3 / 1$ means the pointer moves three times as fast as normal. The fraction can be rounded arbitrarily by the server. Acceleration only takes effect if the pointer moves more than threshold number of pixels at once and only applies to the amount beyond the threshold. Setting a value to -1 restores the default. Other negative values generate a Value error, as does a 0 value for acceleration-denominator.

## ChangeProperty

window: WINDOW<br>property, type: ATOM<br>format: $\{8,16,32\}$<br>mode: $\{$ Replace, Prepend, Append $\}$<br>data: LISTofINT8 or LISTofINT16 or LISTofINT32

## Errors: [ALLOC], [ATOM], [MATCH], [VALUE], [WINDOW]

This request alters property of window. type is uninterpreted by the server. format specifies whether the data should be viewed as a list of 8 -bit, 16 -bit, or 32 -bit quantities so that the server can correctly byte-swap as necessary.
If mode is Replace, the previous property value is discarded. If mode is Prepend or Append, then type and format must match the existing property value, or a [MATCH] error results. If the property is not defined, it is treated as defined with the correct type and format with zero-length data. For Prepend, the data is prepended to any existing data, and for Append, it is appended to any existing data.

This request generates a PropertyNotify event on the window.
The lifetime of a property is not tied to the storing client. Properties remain until explicitly deleted, until the window is destroyed, or until server reset (see Section 2.6).

The maximum size of a property is implementation-dependent and may vary dynamically.

## ChangeSaveSet

window: WINDOW
mode: \{Insert, Delete $\}$
Errors: [MATCH], [VALUE], [WINDOW]
This request adds window to, or removes it from, the client's save-set (see Section 2.6). window must have been created by some other client, or a [MATCH] error results.

When windows are destroyed, the server automatically removes them from the save-set.

## ChangeWindow Attributes

window: WINDOW
value-mask: BITMASK
value-list: LISTofVALUE
Errors: [ACCESS], [COLORMAP], [CURSOR], [MATCH], [PIXMAP], [VALUE], [WINDOW]
value-mask and value-list specify the attributes to change. The values and restrictions are the same as for CreateWindow.
Setting a new background, whether by background-pixmap or background-pixel, overrides any previous background. Setting a new border, whether by border-pixel or border-pixmap, overrides any previous border.
Changing the background does not cause the window contents to be changed. Setting the border or changing the background such that the border tile origin changes causes the border to be repainted. Changing the background of a root window to None or ParentRelative restores the default background pixmap. Changing the border of a root window to CopyFromParent restores the default border pixmap.

Changing the win-gravity does not affect the current position of the window.
Changing the backing-store of an obscured window to WhenMapped or Always or changing the backing-planes, backing-pixel, or save-under of a mapped window may have no immediate effect.

Multiple clients can select input on the same window; their event-masks are disjoint. When an event is generated, it is reported to all interested clients. However, only one client at a time can select for SubstructureRedirect, only one client at a time can select for ResizeRedirect, and only one client at a time can select for ButtonPress. Violating these restrictions produces an [ACCESS] error.

There is only one do-not-propagate-mask for a window, not one per client.
Changing the colormap of a window (by defining a new map, not by changing the contents of the existing map) generates a ColormapNotify event. It is unspecified whether changing the colormap of a visible window has an immediate effect on the screen (see InstallColormap request).

Changing the cursor of a root window to None restores the default cursor.
The order in which attributes are verified and altered is unspecified. If an error is generated, a subset of the attributes may have been altered.

## CirculateWindow

```
    window: WINDOW
    direction: {RaiseLowest,LowerHighest}
Errors: [VALUE], [WINDOW]
```

If some other client has selected SubstructureRedirect on window, then a CirculateRequest event is generated, and no further processing is performed. Otherwise, the following is performed, and then a CirculateNotify event is generated if window is actually restacked.
For RaiseLowest, CirculateWindow raises the lowest mapped child (if any) that is occluded by another child to the top of the stack. For LowerHighest, CirculateWindow lowers the highest mapped child (if any) that occludes another child to the bottom of the stack. Exposure processing is performed on formerly obscured windows.

## ClearArea

window: WINDOW
$x, y$ : INT16
width, height: CARD16
exposures: BOOL

## Errors: [MATCH], [VALUE], [WINDOW]

The $x$ and $y$ coordinates are relative to the window's origin and specify the upper-left corner of the rectangle. If width is 0 , it is replaced with the current width of the window minus $x$. If height is 0 , it is replaced with the current height of the window minus $y$. If the window has a defined background tile, the rectangle is tiled with a plane-mask of all ones and function of Copy and a subwindow-mode of ClipByChildren. If the window has background None, the contents of the window are not changed. In either case, if exposures is True, then one or more exposure events are generated for regions of the rectangle that are either visible or are being retained in a backing store.
It is a [MATCH] error to use an InputOnly window in this request.

## CloseFont

## font: FONT

Errors: [FONT]
This request deletes the association between the resource ID and font. The font itself is freed when no other resource references it.

## ConfigureWindow

window: WINDOW
value-mask: BITMASK
value-list: LISTofVALUE
Errors: [MATCH], [VALUE], [WINDOW]
This request changes the configuration of window. value-mask and value-list specify which values are to be given. The possible values are:

| Attribute | Type |
| :--- | :--- |
| $x$ | INT16 |
| $y$ | INT16 |
| width | CARD16 |
| height | CARD16 |
| border-width | CARD16 |
| sibling |  |
| stack-mode | WINDOW |
|  | \{Above, Below, TopIf, BottomIf, Opposite\} |

The $x$ and $y$ coordinates are relative to the parent's origin and specify the position of the upperleft outer corner of the window. width and height specify the inside size, not including the border, and must be nonzero, or a [VALUE] error results. Those values not specified are taken from the existing geometry of the window. Changing just border-width leaves the outer-left corner of the window in a fixed position but moves the absolute position of the window's origin. It is a [MATCH] error to specify a nonzero border-width for an InputOnly window.
If override-redirect of the window is False and some other client has selected SubstructureRedirect on the parent, a ConfigureRequest event is generated, and no further processing is performed.

If some other client has selected ResizeRedirect on the window and the inside width or height of the window is being changed, a ResizeRequest event is generated, and the current inside width and height are used instead. The override-redirect attribute of the window has no effect on ResizeRedirect and SubstructureRedirect on the parent has precedence over ResizeRedirect on the window.

The geometry of the window is changed as specified, the window is restacked among siblings, and a ConfigureNotify event is generated if the state of the window actually changes. If the inside width or height of the window has actually changed, then children of the window are affected, according to their window gravity. Exposure processing is performed on formerly obscured windows (including the window itself and its inferiors if regions of them were obscured but now are not). Exposure processing is also performed on any new regions of the window (as a result of increasing the width or height) and on any regions where window contents are lost.
If the inside width or height of a window is not changed but the window is moved or its border is changed, then the contents of the window are not lost but move with the window. Changing the inside width or height of the window causes its contents to be moved or lost, depending on the bit-gravity of the window. It also causes children to be reconfigured, depending on their window gravity. For a change of width and height of $W$ and $H$, we define the $[x, y]$ pairs as:

| Direction | Deltas |
| :--- | :--- |
| NorthWest | $[0,0]$ |
| North | $[W / 2,0]$ |
| NorthEast | $[W, 0]$ |
| West | $[0, H / 2]$ |
| Center | $[W / 2, H / 2]$ |
| East | $[W, H / 2]$ |
| SouthWest | $[0, H]$ |
| South | $[W / 2, H]$ |
| SouthEast | $[W, H]$ |

When a window with one of these bit-gravities is resized, the corresponding pair defines the change in position of each pixel in the window. When a window with one of these win-gravities has its parent window resized, the corresponding pair defines the change in position of the window within the parent. This repositioning generates a GravityNotify event. GravityNotify events are generated after the ConfigureNotify event is generated.
A gravity of Static indicates that the contents or origin should not move relative to the origin of the root window. If the change in size of the window is coupled with a change in position of [ $X$, $Y$ ], then for bit-gravity the change in position of each pixel is $[-X,-Y]$ and for win-gravity the change in position of a child when its parent is so resized is $[-X,-Y]$. Static gravity still only takes effect when the width or height of the window is changed, not when the window is simply moved.
A bit-gravity of Forget indicates that the window contents are always discarded after a size change, even if backing-store or save-under has been requested. The window is tiled with its background (except, if no background is defined, the existing screen contents are not altered) and 0 or more exposure events are generated.

The contents and borders of inferiors are not affected by their parent's bit-gravity. A server may ignore bit-gravity and use Forget instead.

A win-gravity of Unmap is like NorthWest, but the child is also unmapped when the parent is resized, and an UnmapNotify event is generated. UnmapNotify events are generated after the ConfigureNotify event is generated.

If a sibling and a stack-mode are specified, the window is restacked as follows:
Above The window is placed just above the sibling.
Below The window is placed just below the sibling.
TopIf If the sibling occludes the window, then the window is placed at the top of the stack.
Bottomif If the window occludes the sibling, then the window is placed at the bottom of the stack.

Opposite If the sibling occludes the window, then the window is placed at the top of the stack. Otherwise, if the window occludes the sibling, then the window is placed at the bottom of the stack.
If a stack-mode is specified but no sibling is specified, the window is restacked as follows:
Above $\quad$ The window is placed at the top of the stack.
Below The window is placed at the bottom of the stack.
TopIf If any sibling occludes the window, then the window is placed at the top of the stack.

BottomIf If the window occludes any sibling, then the window is placed at the bottom of the stack.
Opposite If any sibling occludes the window, then the window is placed at the top of the stack. Otherwise, if the window occludes any sibling, then the window is placed at the bottom of the stack.
It is a [MATCH] error if a sibling is specified without a stack-mode or if the window is not actually a sibling.

The computations for BottomIf, TopIf, and Opposite are performed with respect to the window's final geometry (as controlled by the other parameters to the request), not to its initial geometry.

Attempts to configure a root window have no effect.

## ConvertSelection

```
    selection,target: ATOM
    property: ATOM or None
    requestor: WINDOW
    time: TIMESTAMP or CurrentTime
    Errors: [ATOM], [WINDOW]
```

If selection has an owner, the server sends a SelectionRequest event to that owner. If no owner for selection exists, the server generates a SelectionNotify event to the requestor with property None. The parameters are passed on unchanged in either of the events.

## CopyArea

src-drawable, dst-drawable: DRAWABLE
$g c:$ GCONTEXT
src- $x$, src- $y$ : INT16
width, height: CARD16
$d s t-x, d s t-y$ : INT16
Errors: [DRAWABLE], [GCONTEXT], [MATCH]
This request combines the specified rectangle of src-drawable with the specified rectangle of dstdrawable. The $s r c-x$ and $s r c-y$ coordinates are relative to the origin of src-drawable. dst-x and dst-y are relative to the origin of dst-drawable, each pair specifying the upper-left corner of the rectangle. src-drawable must have the same root and the same depth as dst-drawable, or a [MATCH] error results.

If regions of the source rectangle are obscured and have not been retained in backing store or if regions outside the boundaries of the source drawable are specified, then those regions are not copied, but the following occurs on all corresponding destination regions that are either visible or are retained in backing-store. If dst-drawable is a window with a background other than None, these corresponding destination regions are tiled (with plane-mask of all ones and function Copy) with that background. Regardless of tiling and whether the destination is a window or a pixmap, if graphics-exposures in gc is True, then GraphicsExpose events for all corresponding destination regions are generated.

If graphics-exposures is True but no GraphicsExpose events are generated, then a NoExpose event is generated.
The following components of gc must be provided: function, plane-mask, subwindow-mode, graphics-exposures, clip-x-origin, clip-y-origin, clip-mask.

## CopyColormapAndFree

mid, src-cmap: COLORMAP
Errors: [ALLOC], [COLORMAP], [IDCHOICE]
This request creates a colormap of the same visual type and for the same screen as src-cmap, and it associates identifier mid with it. It also moves all of the client's existing allocations from srccmap to the new colormap with their color values intact and their read-only or writable characteristics intact, and it frees those entries in src-cтap. Color values in other entries in the new colormap are unspecified. If src-cmap was created by the client with alloc=All (see CreateColormap request), then the new colormap is also created with alloc=All, all color values for all entries are copied from src-cmap, and then all entries in src-cmap are freed. If src-cmap was not created by the client with alloc=All, then the allocations to be moved are all those pixels and planes that have been allocated by the client using either AllocColor, AllocNamedColor, AllocColorCells, or AllocColorPlanes, and that have not been freed since they were allocated.

## CopyGC

$s r c-g c, d s t-g c:$ GCONTEXT
value-mask: BITMASK
Errors: [ALLOC], [GCONTEXT], [MATCH], [VALUE]
This request copies components from $s r c-g c$ to $d s t-g c$. The value-mask specifies which components to copy, as for CreateGC. The two graphics contexts must have the same root and the same depth, or a $[\mathrm{MATCH}]$ error results.

## CopyPlane

```
src-drawable,dst-drawable: DRAWABLE
gc: GCONTEXT
src-x, src-y: INT16
width,height: CARD16
dst-x,dst-y: INT16
bit-plane: CARD32
Errors: [DRAWABLE], [GCONTEXT], [MATCH], [VALUE]
```

src-drawable must have the same root as dst-drawable, or a [MATCH] error results, but it need not have the same depth.
bit-plane must have exactly one bit set to 1 and the value of bit-plane must be less than $2^{\mathrm{N}}$, where N is the depth of src-drawable, or a [VALUE] error results.
Effectively, a pixmap of the same depth as dst-drawable and with size specified by the source region is formed using the foreground/background pixels in gc (foreground everywhere bit-plane in src-drawable contains a bit set to 1, background everywhere bit-plane contains a bit set to 0), and the equivalent of a CopyArea is performed, with all the same exposure semantics. This can also be thought of as using the specified region of the source bit-plane as a stipple with a fill-style of OpaqueStippled for filling a rectangular area of the destination.
The following components of $g c$ must be provided: function, plane-mask, foreground, background, subwindow-mode, graphics-exposures, clip-x-origin, clip-y-origin, clip-mask.

## CreateColormap

mid: COLORMAP
visual: VISUALID
window: WINDOW
alloc: $\{$ None, All $\}$
Errors: [ALLOC], [IDCHOICE], [MATCH], [VALUE], [WINDOW]
This request creates a colormap of type visual for the screen on which the window resides and associates the identifier mid with it. visual must be supported by the screen, or a [MATCH] error results. The initial values of the colormap entries are unspecified for classes GrayScale, PseudoColor, and DirectColor. For StaticGray, StaticColor, and TrueColor, the entries have defined values, but those values are specific to the visual and are not defined by the core X protocol. For StaticGray, StaticColor, and TrueColor, alloc must be specified as None, or a [MATCH] error results. For the other classes, if alloc is None, the colormap initially has no allocated entries, and clients can allocate entries.
If alloc is All, then the entire colormap is writable. The initial values of all allocated entries are unspecified. The [ALLOC] error may result if the server cannot allocate a colormap with all cells writable. For GrayScale and PseudoColor, the effect is as if an AllocColorCells request returned all pixel values from 0 to $\mathrm{N}-1$, where N is the colormap-entries value in visual. For DirectColor, the effect is as if an AllocColorPlanes request returned a pixel value of 0 and red-mask, green-mask, and blue-mask values containing the same bits as the corresponding masks in visual. However, these values cannot be freed with FreeColors.

## CreateCursor

cid: CURSOR
source: PIXMAP
mask: PIXMAP or None
fore-red, fore-green, fore-blue: CARD16
back-red, back-green, back-blue: CARD16
$x, y$ : CARD16

## Errors: [ALLOC], [IDCHOICE], [MATCH], [PIXMAP]

This request creates a cursor and associates identifier cid with it. The foreground and background RGB values must be specified, even if the server only has a StaticGray or GrayScale screen. The foreground is used for the bits set to 1 in the source, and the background is used for the bits set to 0 . Both source and mask (if specified) must have depth one, or a [MATCH] error results, but they can have any root. The mask pixmap defines the shape of the cursor. That is, the bits set to 1 in mask define which source pixels are displayed, and where mask has bits set to 0 , the corresponding bits of the source pixmap are ignored. If no mask is given, all pixels of the source are displayed. Any mask must be the same size as the source, or a [MATCH] error results. The $x$ and $y$ coordinates define the hotspot relative to the source's origin and must be a point within the source, or a [MATCH] error results.

The components of the cursor may be transformed in implementation-dependent ways to meet display limitations.
The effect on the cursor of subsequent drawing in the source or mask pixmap is unspecified. It is unspecified whether the server makes a copy of the pixmap.

## CreateGC

## cid: GCONTEXT

drawable: DRAWABLE
value-mask: BITMASK
value-list: LISTofVALUE

## Errors: [ALLOC], [DRAWABLE], [FONT], [IDCHOICE], [MATCH], [PIXMAP], [VALUE]

This request creates a graphics context and assigns the identifier cid to it. The graphics context can be used with any destination drawable having the same root and depth as drawable; use with other drawables results in a [MATCH] error.
value-mask and value-list specify which components to explicitly initialize. The context components are:

| Component | Type |
| :--- | :--- |
| function | \{Clear, And, AndReverse, Copy, AndInverted, NoOp, Xor, Or, Nor, |
|  | Equiv, Invert, OrReverse, CopyInverted, OrInverted, Nand, Set $\}$ |
| plane-mask | CARD32 |
| foreground | CARD32 |
| background | CARD32 |
| line-width | CARD16 |
| line-style | \{Solid,OnOffDash,DoubleDash $\}$ |

| Component |  |
| :--- | :--- |
| cap-style | Type |
| join-style | \{NotLast, Butt, Round, Projecting\} |
| fill-style | \{Miter, Round, Bevel\} |
| fill-rule | \{Solid,Tiled, OpaqueStippled, Stippled $\}$ |
| arc-mode | \{EvenOdd, Winding\} |
| tile | \{Chord, PieSlice $\}$ |
| stipple | PIXMAP |
| tile-stipple-x-origin | PIXMAP |
| tile-stipple-y-origin | INT16 |
| font | FONT |
| subwindow-mode | \{ClipByChildren, IncludeInferiors \} |
| graphics-exposures | BOOL |
| clip- $x$-origin | INT16 |
| clip-y-origin | INT16 |
| clip-mask | PIXMAP or None |
| dash-offset | CARD16 |
| dashes | CARD8 |

In graphics operations, given a source pixel src and destination pixel $d s t$, the result is computed bitwise on corresponding bits of the pixels; that is, a Boolean operation specified by function is performed in each bit plane. plane-mask restricts the operation to a subset of planes, so the result is:
((src function dst) AND plane-mask) OR (dst AND (NOT plane-mask))
The values of foreground, background, and plane-mask are not range-checked but are truncated to the appropriate number of bits.

The meanings of the functions are:

| Function | Operation |
| :--- | :--- |
| Clear | 0 |
| And | src AND $d s t$ |
| AndReverse | src AND (NOT $d s t$ ) |
| Copy | src |
| AndInverted | (NOT src) AND $d s t$ |
| NoOp | $d s t$ |
| Xor | src XOR $d s t$ |
| Or | src OR $d s t$ |
| Nor | (NOT src) AND (NOT $d s t$ ) |
| Equiv | (NOT src) XOR $d s t$ |
| Invert | NOT $d s t$ |
| OrReverse | src OR (NOT $d s t$ ) |
| CopyInverted | NOT $s r c$ |
| OrInverted | (NOT src) OR $d s t$ |
| Nand | (NOT src) OR (NOT $d s t$ ) |
| Set | 1 |

line-width is measured in pixels and can be greater than or equal to one, a wide line, or the special value 0 , a thin line.

Wide lines are drawn centered on the path described by the graphics request. Unless otherwise specified by the join or cap style, the bounding box of a wide line with endpoints $[x 1, y 1],[x 2, y 2]$
and width $w$ is a rectangle with vertices at the following real coordinates:

$$
\begin{aligned}
& \left.\left.\left[x 1-w^{*} \mathrm{sn} / 2\right), y 1+\left(w^{*} \mathrm{cs} / 2\right)\right],\left[x 1+\left(w^{*} \mathrm{sn} / 2\right), y 1-w^{*} \mathrm{cs} / 2\right)\right] \\
& \left.\left.\left[x 2-w^{*} \mathrm{sn} / 2\right), y 2+\left(w^{*} \mathrm{cs} / 2\right)\right],\left[x 2+\left(w^{*} \mathrm{sn} / 2\right), y 2-w^{*} \mathrm{cs} / 2\right)\right]
\end{aligned}
$$

$s n$ is the sine of the angle of the line and $c s$ is the cosine of the angle of the line. A pixel is part of the line (and hence drawn) if the center of the pixel is fully inside the bounding box, which is viewed as having infinitely thin edges. If the center of the pixel is exactly on the bounding box, it is part of the line if and only if the interior is immediately to its right ( $x$ increasing direction). Pixels with centers on a horizontal edge are a special case and are part of the line if and only if the interior or the boundary is immediately below (y increasing direction) and if the interior or the boundary is immediately to the right (x increasing direction). ${ }^{4}$
Thin lines ( 0 line-width) are one-pixel-wide lines drawn using an unspecified algorithm. There are only two constraints on this algorithm. First, if a line is drawn unclipped from $[x 1, y 1]$ to $[x 2$, $y 2]$ and another line is drawn unclipped from $[x 1+d x, y 1+d y]$ to $[x 2+d x, y 2+d y]$, then a point $[x, y]$ is touched by drawing the first line if and only if the point $[x+d x, y+d y]$ is touched by drawing the second line. Second, the effective set of points comprising a line cannot be affected by clipping. Thus, a point is touched in a clipped line if and only if the point lies inside the clipping region and the point would be touched by the line when drawn unclipped.
The endpoints of a wide line with a line-style of Solid can be specified in either order without affecting the pixels drawn (unless a certain order is required to join with subsequent lines).
A line-width of 0 may differ from a line-width of 1 in which pixels are drawn. To obtain precise and uniform results across all displays, a client should always use a line-width of 1 , rather than a line-width of 0 .
line-style defines which sections of a line are drawn:
Solid $\quad$ The full path of the line is drawn.
DoubleDash The full path of the line is drawn, but the even dashes are filled differently than the odd dashes (see fill-style), with Butt cap-style used where even and odd dashes meet.

OnOffDash Only the even dashes are drawn, and cap-style applies to all internal ends of the individual dashes (except NotLast is treated as Butt).
cap-style defines how the endpoints of a path are drawn:
NotLast The result is equivalent to Butt, except that for a line-width of 0 the final endpoint is not drawn.
Butt The result is square at the endpoint (perpendicular to the slope of the line) with no projection beyond.
Round The result is a circular arc with its diameter equal to line-width, centered on the endpoint; it is equivalent to Butt for line-width 0 .

Projecting The result is square at the end, but the path continues beyond the endpoint for a distance equal to half line-width; it is equivalent to Butt for line-width 0.
4. Application Usage: This mathematical model describes the pixels drawn for a wide line and does not imply that trigonometry is required to implement such a model. Real or fixed point arithmetic is recommended for computing the corners of the line endpoints for lines greater than one pixel in width.
join-style defines how corners are drawn for wide lines:
Miter The outer edges of the two lines extend to meet at an angle. However, if the angle is less than 11 degrees, a Bevel join-style is used instead.

Round The result is a circular arc with a diameter equal to line-width, centered on the joinpoint.

Bevel The result is Butt endpoint styles, and then the triangular notch is filled.
For a line with coincident endpoints ( $\mathrm{x} 1=\mathrm{x} 2, \mathrm{y} 1=\mathrm{y} 2$ ), when cap-style is applied to both endpoints, the semantics depend on line-width and cap-style:

| NotLast | thin | Implementation-dependent. However, the intent is that nothing <br> should be drawn. <br> Butt |
| :--- | :--- | :--- |
| Round | thin | Implementation-dependent. However, the intent is that a single <br> pixel should be drawn. <br> Projecting |
| Butt |  |  |
| Round | thin | wide <br> wide |
| Projecting | wide | This is the same as Butt/thin. <br> Nothing is drawn. <br> The closed path is a circle, centered at the endpoint and with a <br> diameter equal to line-width. <br> The closed path is a square, aligned with the coordinate axes, <br> centered at the endpoint and with sides equal to line-width. |

For a line with coincident endpoints $(x 1=x 2$ and $y 1=y 2)$, when join-style is applied at one or both endpoints, the effect is as if the line was removed from the overall path. However, if the total path consists of (or is reduced to) a single point joined with itself, the effect is the same as when cap-style is applied at both endpoints.
tile and stipple represent an infinite 2D plane, with the specified pattern replicated in all dimensions. When that plane is superimposed on the drawable for use in a graphics operation, the upper-left corner of some instance of the pattern is at the coordinates within the drawable specified by the tile/stipple origin. The tile, stipple, and clip origins are interpreted relative to the origin of whatever destination drawable is specified in a graphics request.

The tile pixmap must have the same root and depth as the graphics context being created, or a [MATCH] error results. The stipple pixmap must have depth one and must have the same root as the graphics context being created, or a [MATCH] error results. For fill-style Stippled (but not OpaqueStippled), stipple is tiled in a single plane and acts as an additional clip mask to be ANDed with clip-mask.
fill-style defines the contents of the source for line, text, and fill requests. For all text and fill requests (such as PolyText8, PolyText16, PolyFillRectangle, FillPoly, and PolyFillArc) as well as for line requests with line-style Solid, (for example, PolyLine, PolySegment, PolyRectangle, and PolyArc) and for the even dashes for line requests with line-style of OnOffDash or DoubleDash:

Solid Foreground.
Tiled Tile.
OpaqueStippled A tile with the same width and height as stipple but with background everywhere stipple has a 0 , and with foreground everywhere stipple has a 1.
Stippled Foreground masked by stipple.

For the odd dashes for line requests with line-style of DoubleDash:
Solid Background.
Tiled Same as for even dashes.
OpaqueStippled Same as for even dashes.
Stippled Background masked by stipple.
The dashes value allowed here is a special case of the values settable by SetDashes. A dashes value of $N$ is equivalent to specifying the two element list [ $N, N$ ] in SetDashes. The value must be nonzero, or a [VALUE] error results. The meaning of dash-offset and dashes is explained in the SetDashes request.
clip-mask restricts writes to the destination drawable. Only pixels where clip-mask has bits set to 1 are drawn. Pixels are not drawn outside the area covered by clip-mask or where clip-mask has bits set to 0 . clip-mask affects all graphics requests, but it does not clip sources. The clip-mask origin is interpreted relative to the origin of whatever destination drawable is specified in a graphics request. If a pixmap is specified as clip-mask, it must have depth 1 and have the same root as the graphics context being created, or a [MATCH] error results. If clip-mask is None, then pixels are always drawn, regardless of the clip origin. The clip-mask can also be set with the SetClipRectangles request.
For ClipByChildren, both source and destination windows are additionally clipped by all viewable InputOutput children. For IncludeInferiors, neither source nor destination window is clipped by inferiors. This results in including subwindow contents in the source and drawing through subwindow boundaries of the destination. The semantics of IncludeInferiors, when a mapped inferior has a different depth from the source or destination window, are unspecified.
fill-rule defines which pixels are inside (that is, are drawn) for paths given in FillPoly requests. EvenOdd means a point is inside if an infinite ray with the point as origin crosses the path an odd number of times. For Winding, a point is inside if an infinite ray with the point as origin crosses an unequal number of clockwise and counterclockwise directed path segments. A clockwise directed path segment is one that crosses the ray from left to right as observed from the point. A counter-clockwise segment is one that crosses the ray from right to left as observed from the point.
For both fill rules, a point is infinitely small and the path is an infinitely thin line. A pixel is inside if the center point of the pixel is inside and the center point is not on the boundary. If the center point is on the boundary, the pixel is inside if and only if the polygon interior is immediately to its right ( x increasing direction). Pixels with centers along a horizontal edge are a special case and are inside if and only if the polygon interior is immediately below ( y increasing direction).
arc-mode controls filling in the PolyFillArc request.
The graphics-exposures flag controls GraphicsExpose event generation for CopyArea and CopyPlane requests (and any similar requests defined by extensions).

The default component values are:

| Component |  | Default |
| :--- | :--- | :--- |
| function <br> plane-mask | Copy <br> all ones |  |

| Component | Default |
| :--- | :--- |
| foreground | 0 |
| background | 1 |
| line-width | 0 |
| line-style | Solid |
| cap-style | Butt |
| join-style | Miter |
| fill-style | Solid |
| fill-rule | EvenOdd |
| arc-mode | PieSlice |
| tile | Pixmap of unspecified size filled with foreground pixel (that is, |
|  | client specified pixel if any, else 0) (subsequent changes to |
|  | foreground do not affect this pixmap). |
| stipple | Pixmap of unspecified size filled with ones. |
| tile-stipple- $x$-origin | 0 |
| tile-stipple- $y$-origin | 0 |
| font | An implementation-dependent font. |
| subwindow-mode | ClipByChildren |
| graphics-exposures | True |
| clip- $x$-origin | 0 |
| clip- $y$-origin | 0 |
| clip-mask | None |
| dash-offset | 0 |
| dashes | 4 (that is, the list [4, 4]) |

It is unspecified whether storing a pixmap in a graphics context results in a copy being made. If the pixmap is later used as the destination for a graphics request, the change may be reflected in the graphics context. If the pixmap is used simultaneously in a graphics request as both a destination and as a tile or stipple, the results are unspecified.

## CreateGlyphCursor

cid: CURSOR
source-font: FONT
mask-font: FONT or None
source-char, mask-char: CARD16
fore-red, fore-green, fore-blue: CARD16
back-red, back-green, back-blue: CARD16

## Errors: [ALLOC], [FONT], [IDCHOICE], [VALUE]

This request is similar to CreateCursor, except the source and mask bitmaps are obtained from the specified font glyphs. source-char must be a defined glyph in source-font, and if mask-font is given, mask-char must be a defined glyph in mask-font, or a [VALUE] error results. The mask font and character are optional. The origins of the source and mask (if it is defined) glyphs are positioned coincidently and define the hotspot. The source and mask need not have the same bounding box metrics, and there is no restriction on the placement of the hotspot relative to the bounding boxes. If no mask is given, all pixels of the source are displayed. For 2-byte matrix fonts, the 16-bit value should be formed with byte1 in the most-significant byte and byte 2 in the least-significant byte.

The components of the cursor may be transformed arbitrarily to meet display limitations.

The fonts can be freed immediately if no further explicit references to them are to be made.

## CreatePixmap

```
pid: PIXMAP
drawable: DRAWABLE
depth: CARD8
width, height: CARD16
Errors: [ALLOC], [DRAWABLE], [IDCHOICE], [VALUE]
```

This request creates a pixmap and assigns the identifier pid to it. width and height must be nonzero, or a [VALUE] error results. depth must be one of the depths supported by the screen of drawable, or a [VALUE] error results. The initial contents of the pixmap are unspecified.
It is valid to pass an InputOnly window as a drawable to this request.

## CreateWindow

```
    wid, parent: WINDOW
    class: {InputOutput,InputOnly, CopyFromParent}
    depth: CARD8
    visual: VISUALID or CopyFromParent
    x,y: INT16
    width, height,border-width: CARD16
    value-mask: BITMASK
    value-list: LISTofVALUE
Errors: [ALLOC], [COLORMAP], [CURSOR], [IDCHOICE], [MATCH], [PIXMAP],
[VALUE], [WINDOW]
```

This request creates an unmapped window and assigns the identifier wid to it.
A class of CopyFromParent means the class is taken from the parent. A depth of 0 for class InputOutput or CopyFromParent means the depth is taken from the parent. A visual of CopyFromParent means the visual type is taken from the parent. For class InputOutput, visual and depth must be a combination supported for the screen, or a [MATCH] error results. depth need not be the same as the parent, but the parent must not be of class InputOnly, or a [MATCH] error results. For class InputOnly, depth must be 0, or a [MATCH] error results; and visual must be supported for the screen, or a [MATCH] error results. However, the parent can have any depth and class.

The server essentially acts as if InputOnly windows do not exist for the purposes of graphics requests, exposure processing, and VisibilityNotify events. An InputOnly window cannot be used as a drawable.

The coordinate system has the $x$ axis horizontal and the $y$ axis vertical, with the origin [0, 0] at the upper left. Coordinates are integral, in terms of pixels, and coincide with pixel centers. Each window and pixmap has its own coordinate system. For a window, the origin is inside the border at the inside upper left.

The $x$ and $y$ coordinates for the window are relative to the parent's origin and specify the position of the upper-left outer corner of the window (not the origin). width and height specify the inside size (not including the border) and must be nonzero, or a [VALUE] error results. border-width for an InputOnly window must be 0, or a [MATCH] error results.
The window is placed on top in the stacking order with respect to siblings.
value-mask and value-list specify attributes of the window that are to be explicitly initialized. The possible values, and default values when attributes are not explicitly initialized, are as follows:

| Attribute | Type | Default |
| :--- | :--- | :--- |
| background-pixmap | PIXMAP or None or ParentRelative | None |
| background-pixel | CARD32 |  |
| border-pixmap | PIXMAP or CopyFromParent | CopyFromParent |
| border-pixel | CARD32 |  |
| bit-gravity | BITGRAVITY | Forget |
| win-gravity | WINGRAVITY | NorthWest |
| backing-store | \{NotUseful, WhenMapped, Always $\}$ | NotUseful |
| backing-planes | CARD32 | All ones |
| backing-pixel | CARD32 | 0 |
| save-under | BOOL | False |
| event-mask | SETofEVENT | Empty set |
| do-not-propagate-mask | SETofDEVICEEVENT | Empty set |
| override-redirect | BOOL | False |
| colormap | COLORMAP or CopyFromParent | CopyFromParent |
| cursor | CURSOR or None | None |

Only the following attributes are defined for InputOnly windows:

- win-gravity
- event-mask
- do-not-propagate-mask
- override-redirect
- cursor

It is a $[\mathrm{MATCH}]$ error to specify any other attributes for InputOnly windows.
If background-pixmap is given, it overrides the default background-pixmap. The background pixmap and the window must have the same root and the same depth, or a [MATCH] error results. If background None is specified, the window has no defined background. If background ParentRelative is specified, the parent's background is used, but the window must have the same depth as the parent, or a [MATCH] error results. If the parent has background None, then the window also has background None. A copy of the parent's background is not made. The parent's background is reexamined each time the window background is required.
If background-pixel is given, it overrides the default background-pixmap and any background-pixmap given explicitly. The background-pixel value is not range-checked but is truncated to the appropriate number of bits. For a ParentRelative background, the background tile origin always aligns with the parent's background tile origin. Otherwise, the background tile origin is always the window origin.

When no valid contents are available for regions of a window and the regions are either visible or the server is maintaining backing store, the server automatically tiles the regions with the window's background unless the window has a background of None. If the background is None, the screen contents of other windows of the same depth as the window are unchanged if the contents come from the parent of the window or an inferior of the parent; otherwise, the initial contents of the exposed regions are unspecified. Expose events are then generated for the regions, even if the background is None.
The border tile origin is always the same as the background tile origin. If border-pixmap is given, it overrides the default border-pixmap. The border pixmap and the window must have the same
root and the same depth, or a [MATCH] error results. If CopyFromParent is given, the parent's border pixmap is copied and subsequent changes to the parent's border attribute do not affect the child. In this case, the window must have the same depth as the parent, or a [MATCH] error results. The pixmap might be copied by sharing the same pixmap object between the child and parent or by making a complete copy of the pixmap contents. If border-pixel is given, it overrides the default border-pixmap and any border-pixmap given explicitly. Range checking is not performed on the border-pixel value; it is truncated to the appropriate number of bits.
Output to a window is always clipped to the inside of the window, so that the border is never affected.
bit-gravity defines which region of the window should be retained if the window is resized, and win-gravity defines how the window should be repositioned if the parent is resized (see ConfigureWindow request).
A backing-store of WhenMapped advises the server that maintaining contents of obscured regions when the window is mapped may be beneficial. A backing-store of Always advises the server that maintaining contents even when the window is unmapped may be beneficial. In this case, the server may generate an exposure event when the window is created. A value of NotUseful advises the server that maintaining contents is unnecessary, although a server may still maintain contents while the window is mapped. ${ }^{5}$
If save-under is True, the server is advised that when this window is mapped, saving the contents of windows it obscures may be beneficial.
When the contents of obscured regions of a window are being maintained, regions obscured by non-inferior windows are included in the destination (and source, when the window is the source) of graphics requests, but regions obscured by inferior windows are not included.
backing-planes indicates (with bits set to 1 ) which bit planes of the window hold dynamic data that must be preserved in backing store and during save-unders. backing-pixel specifies what value to use in planes not covered by backing-planes. The server is free to save only the specified bit planes in backing-store or save-under and regenerate the remaining planes with the specified pixel value. Any bits beyond the specified depth of the window in these values are ignored.
event-mask defines which events the client is interested in for this window (or for some event types, inferiors of the window). The do-not-propagate-mask defines which events should not be propagated to ancestor windows when no client has the event type selected in this window.
override-redirect specifies whether map and configure requests on this window should override a SubstructureRedirect on the parent, typically to inform a window manager not to tamper with the window.
colormap specifies the colormap that best reflects the true colors of the window. Servers capable of supporting multiple hardware colormaps may use this information, and window managers may use it for InstallColormap requests. colormap must have the same visual type and root as the window, or a [MATCH] error results. If CopyFromParent is specified, the parent's colormap is copied (subsequent changes to the parent's colormap attribute do not affect the child). However, the window must have the same visual type as the parent, or a [MATCH] error results; and the parent must not have a colormap of None, or a [MATCH] error results. For an explanation of

[^2]None, see FreeColormap. colormap is copied by sharing the colormap object between the child and the parent, not by making a complete copy of the colormap contents.
If a cursor is specified, it is used whenever the pointer is in the window. If None is specified, the parent's cursor is used when the pointer is in the window, and any change in the parent's cursor causes an immediate change in the displayed cursor.
This request generates a CreateNotify event.
The background and border pixmaps and the cursor may be freed immediately if no further explicit references to them are to be made.
The effect on the window state of subsequent drawing into the background or border pixmap is unspecified. It is unspecified whether the server makes a copy of the pixmap.

## DeleteProperty

window: WINDOW
property: ATOM
Errors: [ATOM], [WINDOW]
If property exists, this request deletes it from window and generates a PropertyNotify event on window.

## DestroySubwindows

window: WINDOW
Errors: [WINDOW]
This request performs a DestroyWindow request on all children of window, in bottom-to-top stacking order.

## DestroyWindow

window: WINDOW
Errors: [WINDOW]
If window is mapped, an UnmapWindow request is performed automatically. window and all inferiors are then destroyed, and a DestroyNotify event is generated for each window. The ordering of the DestroyNotify events is such that for any given window, DestroyNotify is generated on all inferiors of the window before being generated on the window itself. The ordering among siblings and across subhierarchies is otherwise unspecified.
Normal exposure processing on formerly obscured windows is performed.
If the window is a root window, this request has no effect.

## FillPoly

drawable: DRAWABLE
$g c:$ GCONTEXT
shape: \{Complex, Nonconvex, Convex\}
coordinate-mode: \{Origin, Previous\}
points: LISTofPOINT
Errors: [DRAWABLE], [GCONTEXT], [MATCH], [VALUE]

This request fills the region closed by the specified path. The path is closed automatically if the last point in the list does not coincide with the first point. No pixel of the region is drawn more than once.

The first point is always relative to the drawable's origin. The rest are relative either to that origin or the previous point, depending on coordinate-mode

If shape is Complex, the path may self-intersect. Contiguous coincident points in the path are not treated as self-intersection. Nonconvex means the path does not self-intersect, but the shape is not wholly convex. If known by the client, specifying Nonconvex over Complex may improve performance. If Nonconvex is specified for a self-intersecting path, the graphics results are unspecified. Convex means that for every pair of points inside the polygon, the line segment connecting them does not intersect the path. If known by the client, specifying Convex may improve performance. If Convex is specified for a path that is not convex, the results are unspecified.
The following components of gc must be provided: function, plane-mask, fill-style, fill-rule, subwindow-mode, clip-x-origin, clip-y-origin, clip-mask.

The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple- $x$-origin, tile-stipple- $y$-origin.

## ForceScreenSaver

mode: $\{$ Activate, Reset $\}$
Errors: [VALUE]
If mode is Activate and the screen-saver is currently deactivated, then the screen-saver is activated (even if the screen-saver has been disabled with a timeout value of 0 ). If mode is Reset and the screen-saver is currently enabled, then the screen-saver is deactivated (if it was activated), and the activation timer is reset to its initial state as if device input had just been received.

## FreeColormap

cmap: COLORMAP

## Errors: [COLORMAP]

This request deletes the association between the resource ID and cmap and frees the colormap storage. If cmap is an installed map for a screen, it is uninstalled. If cmap is defined as the colormap for a window (by means of CreateWindow or ChangeWindowAttributes), the colormap for the window is changed to None, and a ColormapNotify event is generated. The colors displayed for a window with a colormap of None are unspecified.
This request has no effect on a default colormap for a screen.

## FreeColors

cmap: COLORMAP

pixels: LISTofCARD32
plane-mask: CARD32

## Errors: [ACCESS], [COLORMAP], [VALUE]

plane-mask should not have any bits in common with any of the pixels. The set of all pixels is produced by ORing together subsets of plane-mask with the pixels. The request frees all of these pixels that were allocated by the client (using AllocColor, AllocNamedColor, AllocColorCells, and AllocColorPlanes). ${ }^{6}$

All specified pixels that are allocated by the client in cmap are freed, even if one or more pixels produce an error. A [VALUE] error is generated if a specified pixel is not a valid index into cmap. An [ACCESS] error is generated if a specified pixel is not allocated by the client (that is, is unallocated or is only allocated by another client) or if the colormap was created with all entries writable (using an alloc value of All in CreateColormap). If more than one pixel is in error, it is unspecified which pixel is reported.

## FreeCursor

```
        cursor: CURSOR
```

Errors: [CURSOR]
This request deletes the association between the resource ID and cursor. The cursor storage is freed when no other resource references it.

## FreeGC

## gc: GCONTEXT

Errors: [GCONTEXT]
This request deletes the association between the resource ID and $g c$ and destroys the graphics context.

## FreePixmap

pixmap: PIXMAP
Errors: [PIXMAP]
This request deletes the association between the resource ID and pixmap. The pixmap storage is freed when no other resource references it.

## GetAtomName

```
    atom: ATOM
    ->
    name:STRING8
    Errors: [ATOM]
```

This request returns the name for atom.

[^3]
## GetFontPath

```
->
path: LISTofSTRING8
```

This request returns the current search path for fonts.

## GetGeometry

drawable: DRAWABLE<br>$\rightarrow$<br>root: WINDOW<br>depth: CARD8<br>$x, y:$ INT16<br>width, height, border-width: CARD16

## Errors: [DRAWABLE]

This request returns the root and current geometry of drawable. depth is the number of bits per pixel for the object. $x, y$, and border-width are always 0 for pixmaps. For a window, the $x$ and $y$ coordinates specify the upper-left outer corner of the window relative to its parent's origin, and width and height specify the inside size, not including the border.
It is valid to pass an InputOnly window as a drawable to this request.

## GetImage

drawable: DRAWABLE
$x, y$ : INT16
width, height: CARD16
plane-mask: CARD32
format: $\{$ XYPixmap, ZPixmap\}
$\rightarrow$
depth: CARD8
visual: VISUALID or None
data: LISTofBYTE
Errors: [DRAWABLE], [MATCH], [VALUE]
This request returns the contents of the given rectangle of drawable in format. The $x$ and $y$ coordinates are relative to the origin of drawable and define the upper-left corner of the rectangle. If XYPixmap is specified, only the bit planes specified in plane-mask are transmitted, with the planes appearing from most-significant to least-significant in bit order. If ZPixmap is specified, then bits in all planes not specified in plane-mask are transmitted as 0 . Range checking is not performed on plane-mask; extraneous bits are ignored. The returned depth is as specified when drawable was created and is the same as a depth component in a FORMAT structure (in the connection setup), not a bits-per-pixel component. If drawable is a window, its visual type is returned. If drawable is a pixmap, the visual is None.

If drawable is a pixmap, then the given rectangle must be wholly contained within the pixmap, or a [MATCH] error results. If drawable is a window, the window must be viewable, and it must be the case that, if there were no overlapping or inferior windows, the specified rectangle of the window would be fully visible on the screen and wholly contained within the outside edges of the window, or a [MATCH] error results. The borders of the window can be included and read with this request. If the window has a backing store, then the backing-store contents are returned for regions of the window that are obscured by non-inferior windows; otherwise, the returned contents of such obscured regions are unspecified. The returned contents of visible regions of
inferiors of different depth other than the specified window are unspecified. The pointer cursor image is not included in the contents returned.

## GetInputFocus

$\rightarrow$
focus: WINDOW or PointerRoot or None revert-to: \{Parent, PointerRoot, None\}
This request returns the current focus state.

## GetKeyboardControl

## $\rightarrow$

key-click-percent: CARD8
bell-percent: CARD8
bell-pitch: CARD16
bell-duration: CARD16
led-mask: CARD32
global-auto-repeat: $\{O n$, Off $\}$
auto-repeats: LISTofCARD8
This request returns the current control values for the keyboard. For the LEDs, the leastsignificant bit of led-mask corresponds to LED one, and each one bit in led-mask indicates an LED that is lit. auto-repeats is a bit vector; each one bit indicates that auto-repeat is enabled for the corresponding key. The vector is represented as 32 bytes. Byte N (from 0 ) contains the bits for keys 8 N to $8 \mathrm{~N}+7$, with the least-significant bit in the byte representing key 8 N .

## GetKeyboardMapping

```
    first-keycode: KEYCODE
    count:CARD8
->
    keysyms-per-keycode: CARD8
    keysyms: LISTofKEYSYM
    Errors: [VALUE]
```

This request returns the symbols for the specified number of keycodes, starting with first-keycode. This must be greater than or equal to min-keycode as returned in the connection setup, or a [VALUE] error results; and:

$$
\text { first-keycode }+ \text { count }-1
$$

must be less than or equal to max-keycode as returned in the connection setup, or a [VALUE] error results. The number of elements in the keysyms list is:
count*keysyms-per-keycode
and KEYSYM number N (counting from 0 ) for keycode K has an index (counting from 0 ) of:

$$
(K-\text { first-keycode }) * \text { keysyms-per-keycode }+N
$$

in keysyms. The server chooses a value of keysyms-per-keycode that is large enough to report all requested symbols. A special KEYSYM value of NoSymbol fills unused elements for individual keycodes.

## GetModifierMapping

$$
\rightarrow
$$

keycodes-per-modifier: CARD8
keycodes: LISTofKEYCODE
This request returns the keycodes of the keys being used as modifiers. The number of keycodes in the list is $8^{*}$ keycodes-per-modifier. The keycodes are divided into eight sets, with each set containing keycodes-per-modifier elements. The sets are assigned to the modifiers Shift, Lock, Control, Mod1, Mod2, Mod3, Mod4, and Mod5, in order. The server chooses a value of keycodes-per-modifier value and uses zeros to fill unused elements within each set. If only 0 values are given in a set, the use of the corresponding modifier has been disabled. The order of keycodes within each set is unspecified.

## GetMotionEvents

```
    start, stop: TIMESTAMP or CurrentTime
    window: WINDOW
->
    events: LISTofTIMECOORD
where:
TIMECOORD: [x,y: INT16
    time: TIMESTAMP]
Errors: [WINDOW]
```

This request returns all events in the motion history buffer that occurred from start up to and including stop, and whose coordinates are within the borders of window at its present placement. The $x$ and $y$ coordinates are reported relative to the origin of window.

If start is later than stop or if start is in the future, no events are returned. If stop is in the future, it is equivalent to specifying CurrentTime.

## GetPointerControl

$\rightarrow$
acceleration-numerator, acceleration-denominator: CARD16
threshold: CARD16
This request returns the current acceleration and threshold for the pointer. The server may return different values of acceleration-numerator and acceleration-denominator from those most recently set with ChangePointerControl.

## GetPointerMapping

$\rightarrow$
map: LISTofCARD8
This request returns the current mapping of the pointer. Elements of the list are indexed starting from one. The length of the list indicates the number of physical buttons.
The nominal mapping for a pointer is the identity mapping: map $[i]=i$.

## GetProperty

```
    window: WINDOW
    property: ATOM
    type: ATOM or AnyPropertyType
    long-offset, long-length: CARD32
    delete: BOOL
\(\rightarrow\)
    type: ATOM or None
    format: \(\{0,8,16,32\}\)
    bytes-after: CARD32
    value: LISTofINT8 or LISTofINT16 or LISTofINT32
Errors: [ATOM], [VALUE], [WINDOW]
```

If property does not exist for window, then the return type is None, format and bytes-after are 0 , and value is empty. The delete parameter is ignored in this case.

If property exists but its type does not match the specified type, then the return type is the actual type of the property, format is the actual format of the property (never 0), bytes-after is the length of the property in bytes (even if format is 16 or 32 ), and value is empty. The delete parameter is ignored in this case.
If property exists and either AnyPropertyType is specified or type matches the actual type of the property, then the return type is the actual type of the property, format is the actual format of the property (never 0), and bytes-after and value are as follows, given:
$N$ Actual length of the stored property in bytes (even if format is 16 or 32 ).
I $4^{*}$ long-offset
T N-I
$L \quad \operatorname{MINIMUM}(\mathrm{~T}, 4 *$ long-length $)$
A $N-(I+L)$
The returned value starts at byte index I in the property (indexing from 0), and its length in bytes is $L$. However, it is a [VALUE] error if long-offset is given such that $L$ is negative. The value of bytes-after is $A$, giving the number of trailing unread bytes in the stored property. If delete is True and bytes-after is 0 , the property is also deleted from the window, and a PropertyNotify event is generated on the window.

## GetScreenSaver

$\rightarrow$
timeout, interval: CARD16
prefer-blanking: $\{$ Yes, No\}
allow-exposures: $\{Y e s, N o\}$
This request returns the current screen-saver control values.

## GetSelectionOwner

```
    selection: ATOM
->
    owner: WINDOW or None
Errors: [ATOM]
```

This request returns any current owner window of selection, or None if there is no owner.

## GetWindowAttributes

```
    window: WINDOW
->
    visual: VISUALID
    class: {InputOutput, InputOnly}
    bit-gravity: BITGRAVITY
    win-gravity: WINGRAVITY
    backing-store: {NotUseful, WhenMapped, Always}
    backing-planes: CARD32
    backing-pixel: CARD32
    save-under: BOOL
    colormap: COLORMAP or None
    map-is-installed: BOOL
    map-state: {Unmapped, Unviewable,Viewable}
    all-event-masks, your-event-mask: SETofEVENT
    do-not-propagate-mask: SETofDEVICEEVENT
    override-redirect: BOOL
```

Errors: [WINDOW]

This request returns the current attributes of window. A window is Unviewable if it is mapped but some ancestor is unmapped. The returned all-event-masks is the inclusive-OR of all event masks selected on the window by clients, and your-event-mask is the event mask selected by the querying client.

## GrabButton

modifiers: SETofKEYMASK or AnyModifier
button: BUTTON or AnyButton
grab-window: WINDOW
owner-events: BOOL
event-mask: SETofPOINTEREVENT
pointer-mode, keyboard-mode: \{Synchronous, Asynchronous\}
confine-to: WINDOW or None
cursor: CURSOR or None
Errors: [ACCESS], [CURSOR], [VALUE], [WINDOW]
This request establishes a passive grab. In the future, the pointer is actively grabbed as described in GrabPointer, the last-pointer-grab time is set to the time at which the button was pressed (as transmitted in the ButtonPress event), and the ButtonPress event is reported if all of the following conditions are true:

- The pointer is not grabbed and button is logically pressed when the specified modifier keys are logically down, and no other buttons or modifier keys are logically down.
- grab-window contains the pointer.
- Any confine-to window is viewable.
- A passive grab on the same button/key combination does not exist on any ancestor of grabwindow.

The interpretation of the remaining parameters is the same as for GrabPointer. The active grab is terminated automatically when the logical state of the pointer has all buttons released, independent of the logical state of modifier keys. The logical state of a device (as seen by means of the protocol) may lag the physical state if device event processing is frozen.
This request overrides all previous passive grabs by the same client on the same button/key combinations on the same window. A modifier of AnyModifier is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). It is not required that all specified modifiers have currently assigned keycodes. A button of AnyButton is equivalent to issuing the request for all possible buttons. Otherwise, it is not required that the button specified currently be assigned to a physical button.

An [ACCESS] error is generated if some other client has already issued a GrabButton request with the same button/key combination on the same window. When using AnyModifier or AnyButton, the request fails completely (no grabs are established), and an [ACCESS] error is generated if there is a conflicting grab for any combination. The request has no effect on an active grab.

## GrabKey

```
key: KEYCODE or AnyKey
modifiers: SETofKEYMASK or AnyModifier
grab-window: WINDOW
owner-events: BOOL
pointer-mode, keyboard-mode: {Synchronous, Asynchronous}
Errors: [ACCESS], [VALUE], [WINDOW]
```

This request establishes a passive grab on the keyboard. In the future, the keyboard is actively grabbed as described in GrabKeyboard, the last-keyboard-grab time is set to the time at which the key was pressed (as transmitted in the KeyPress event), and the KeyPress event is reported if all of the following conditions are true:

- The keyboard is not grabbed and key (which can itself be a modifier key) is logically pressed when modifiers are logically down, and no other modifier keys are logically down.
- Either grab-window is an ancestor of (or is) the focus window, or grab-window is a descendent of the focus window and contains the pointer.
- A passive grab on the same key combination does not exist on any ancestor of grab-window.

The interpretation of the remaining parameters is the same as for GrabKeyboard. The active grab is terminated automatically when the logical state of the keyboard has key released, independent of the logical state of modifier keys. The logical state of a device (as seen by means of the protocol) may lag the physical state if device event processing is frozen.
This request overrides all previous passive grabs by the same client on the same key combinations on the same window. A modifier of AnyModifier is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). It is not required that all modifiers specified have currently assigned keycodes. A key of AnyKey is equivalent to issuing the request for all possible keycodes. Otherwise, the key must be in the range specified by min-keycode and max-keycode in the connection setup, or a [VALUE] error
results.
An [ACCESS] error is generated if some other client has issued a GrabKey with the same key combination on the same window. When using AnyModifier or AnyKey, the request fails completely (no grabs are established), and an [ACCESS] error is generated if there is a conflicting grab for any combination.

## GrabKeyboard

```
    grab-window: WINDOW
    owner-events: BOOL
    pointer-mode, keyboard-mode: {Synchronous, Asynchronous}
    time: TIMESTAMP or CurrentTime
->
    status: {Success, AlreadyGrabbed, Frozen, InvalidTime, NotViewable}
```

## Errors: [VALUE], [WINDOW]

This request actively grabs control of the keyboard. Further key events are reported only to the grabbing client. This request overrides any active keyboard grab by this client.
If owner-events is False, all generated key events are reported with respect to grab-window. If owner-events is True and if a generated key event would normally be reported to this client, it is reported normally. Otherwise, the event is reported with respect to grab-window. Both KeyPress and KeyRelease events are always reported, independent of any event selection made by the client.
If keyboard-mode is Asynchronous, keyboard event processing continues normally. If the keyboard is currently frozen by this client, then processing of keyboard events is resumed. If keyboard-mode is Synchronous, the state of the keyboard (as seen by means of the protocol) appears to freeze. No further keyboard events are generated by the server until the grabbing client issues a releasing AllowEvents request or until the keyboard grab is released. Actual keyboard changes are not lost while the keyboard is frozen. They are queued for later processing.

If pointer-mode is Asynchronous, pointer event processing is unaffected by activation of the grab. If pointer-mode is Synchronous, the state of the pointer (as seen by means of the protocol) appears to freeze. No further pointer events are generated by the server until the grabbing client issues a releasing AllowEvents request or until the keyboard grab is released. Actual pointer changes are not lost while the pointer is frozen. They are queued for later processing.
This request may generate FocusIn and FocusOut events.
The request fails with status AlreadyGrabbed if the keyboard is actively grabbed by some other client. The request fails with status Frozen if the keyboard is frozen by an active grab of another client. The request fails with status NotViewable if grab-window is unviewable. The request fails with status InvalidTime if time is earlier than the last-keyboard-grab time or later than the current server time. Otherwise, the last-keyboard-grab time is set to time with CurrentTime replaced by the current server time.

## GrabPointer

```
    grab-window: WINDOW
    owner-events: BOOL
    event-mask: SETofPOINTEREVENT
    pointer-mode, keyboard-mode: {Synchronous, Asynchronous}
    confine-to: WINDOW or None
    cursor: CURSOR or None
    time: TIMESTAMP or CurrentTime
->
    status: {Success, AlreadyGrabbed, Frozen, InvalidTime, NotViewable}
Errors: [CURSOR], [VALUE], [WINDOW]
```

This request actively grabs control of the pointer. Further pointer events are only reported to the grabbing client. The request overrides any active pointer grab by this client.
If owner-events is False, all generated pointer events are reported with respect to grab-window and are only reported if selected by event-mask. If owner-events is True and a generated pointer event would normally be reported to this client, it is reported normally. Otherwise, the event is reported with respect to the grab-window and is only reported if selected by event-mask. For either value of owner-events, unreported events are discarded.

If pointer-mode is Asynchronous, pointer event processing continues normally. If the pointer is currently frozen by this client, then processing of pointer events is resumed. If pointer-mode is Synchronous, the state of the pointer (as seen by means of the protocol) appears to freeze, and no further pointer events are generated by the server until the grabbing client issues a releasing AllowEvents request or until the pointer grab is released. Actual pointer changes are not lost while the pointer is frozen. They are queued for later processing.
If keyboard-mode is Asynchronous, keyboard event processing is unaffected by activation of the grab. If keyboard-mode is Synchronous, the state of the keyboard (as seen by means of the protocol) appears to freeze, and no further keyboard events are generated by the server until the grabbing client issues a releasing AllowEvents request or until the pointer grab is released. Actual keyboard changes are not lost while the keyboard is frozen. They are queued for later processing.
If a cursor is specified, then it is displayed regardless of what window the pointer is in. If no cursor is specified, then when the pointer is in grab-window or one of its subwindows, the normal cursor for that window is displayed. Otherwise, the cursor for grab-window is displayed.
If confine-to is specified, then the pointer is restricted to stay contained in that window. The confine-to window need have no relationship to grab-window. If the pointer is not initially in confine-to, then it is warped automatically to the closest edge, generating enter/leave events normally, just before the grab activates. If confine-to is subsequently reconfigured, the pointer is warped automatically as necessary to keep it contained in the window.

This request generates EnterNotify and LeaveNotify events.
The request fails with status AlreadyGrabbed if the pointer is actively grabbed by some other client. The request fails with status Frozen if the pointer is frozen by an active grab of another client. The request fails with status NotViewable if grab-window or confine-to is unviewable or if confine-to lies completely outside the boundaries of the root window. The request fails with status InvalidTime if time is earlier than the last-pointer-grab time or later than the current server time. Otherwise, the last-pointer-grab time is set to the specified time, with CurrentTime replaced by the current server time.

## GrabServer

(No request-specific parameters.)
This request disables processing of requests and close-downs on all connections other than the one this request arrived on.

## ImageText8

```
    drawable: DRAWABLE
    gc: GCONTEXT
    x,y: INT16
    string:STRING8
    Errors: [DRAWABLE], [GCONTEXT], [MATCH]
```

The $x$ and $y$ coordinates are relative to the drawable's origin and specify the baseline starting position (the initial character origin). The effect is first to fill a destination rectangle with the background pixel defined in $g c$ and then to paint the text with the foreground pixel. The upperleft corner of the filled rectangle is at. [ $x, y$-font-ascent], the width is overall-width, and the height is font-ascent+font-descent; where overall-width, font-ascent, and font-descent are the values QueryTextExtents would return for $g c$ and string.
function and fill-style defined in $g c$ are ignored for this request. The effective function is Copy, and the effective fill-style is Solid.
For fonts defined with 2-byte matrix indexing, each STRING8 byte is interpreted as a byte2 value of a CHAR2B with a byte1 value of 0 .
The following components of $g c$ must be provided: plane-mask, foreground, background, font, subwindow-mode, clip-x-origin, clip-y-origin, clip-mask.

## ImageText16

drawable: DRAWABLE
$g c:$ GCONTEXT
$x, y$ : INT16
string: STRING16

## Errors: [DRAWABLE], [GCONTEXT], [MATCH]

This request is similar to ImageText8, except 2-byte characters are used. For fonts defined with linear indexing rather than 2-byte matrix indexing, the server interprets each CHAR2B as a 16-bit number that has been transmitted most-significant byte first.

## InstallColormap

## cmap: COLORMAP

Errors: [COLORMAP]
This request makes cmap an installed map for its screen. All windows associated with cmap immediately display with correct colors. As a side effect, additional colormaps might be implicitly installed or uninstalled by the server. Which other colormaps get installed or uninstalled is implementation-dependent, except that the required list must remain installed.
If cmap is not already an installed map, a ColormapNotify event is generated on every window having cmap as an attribute. In addition, for every other colormap that is installed or uninstalled as a result of the request, a ColormapNotify event is generated on every window having that colormap as an attribute.

At any time, there is a subset of the installed maps that are conceptually an ordered list called the required list. The length of the required list is at most M , where M is the min-installed-maps specified for the screen in the connection setup. The required list is maintained as follows. When a colormap is an explicit parameter to InstallColormap, it is added to the head of the list; the list is truncated at the tail, if necessary, to keep its length to at most M . When a colormap is an explicit parameter to UninstallColormap and it is in the required list, it is removed from the list. A colormap is not added to the required list when it is installed implicitly by the server, and the server cannot implicitly uninstall a colormap that is in the required list.
Initially the default colormap for a screen is installed (but is not in the required list).

## InternAtom

```
    name: STRING8
    only-if-exists: BOOL
->
    atom: ATOM or None
Errors: [ALLOC], [VALUE]
```

This request returns the atom for name. If only-if-exists is False, then the atom is created if it does not exist.

The lifetime of an atom is not tied to the interning client. Atoms remain defined until server reset (see Section 2.6).
name is compared, case-sensitively, against stored atoms. If name does not use the ISO Latin-1 encoding, the results are implementation-dependent.

## KillClient

resource: CARD32 or AllTemporary

## Errors: [VALUE]

If resource is a valid resource ID, KillClient forces a close-down of the client that created resource. If the client has already terminated in either RetainPermanent or RetainTemporary mode, all the client's resources are destroyed (see Section 2.6). If AllTemporary is specified, then the resources of all clients that have terminated in RetainTemporary are destroyed.

## ListExtensions

## $\rightarrow$

names: LISTofSTRING8
This request returns a list of all X Window System extensions supported by the server.

## ListFonts

pattern: STRING8
max-names: CARD16
$\rightarrow$
names: LISTofSTRING8
This request returns a list of up to max-names names of available fonts (as controlled by the font search path; see the SetFontPath request) that match pattern. In pattern, the character \#0x3F (ASCII '?') matches any single character, and \#0x2a (ASCII '*') matches any number of characters. The returned names are in lowercase.
pattern is compared, case-insensitively, to the names of available fonts. If pattern does not use the ISO Latin-1 encoding, the results are implementation-dependent.

## ListFontsWithInfo

pattern: STRING8
max-names: CARD16
$\rightarrow+$
name: STRING8
info: FONTINFO
replies-hint: CARD32
This request is similar to ListFonts, but it also returns information about each font. The information returned for each font is identical to what QueryFont would return except that the per-character metrics are not returned. This request can generate multiple replies. With each reply, replies-hint may indicate how many more fonts remain. This number is a hint only and may be larger or smaller than the number of fonts actually returned. A 0 value does not guarantee that the reply is the last one. After the font replies, a reply with a zero-length name is sent to indicate the end of the reply sequence.

## ListHosts

$$
\rightarrow
$$

mode: $\{$ Enabled, Disabled $\}$
hosts: LISTofHOST
This request returns the hosts on the access control list and indicates whether use of the list at connection setup is currently enabled or disabled.
Each element of hosts is padded to a multiple of 4 bytes.

## ListInstalledColormaps

```
    window: WINDOW
->
    cmaps: LISTofCOLORMAP
Errors: [WINDOW]
```

This request returns a list of the currently installed colormaps for the screen of window. The order of colormaps is not significant, and there is no explicit indication of the required list (see InstallColormap request).

## ListProperties

window: WINDOW
$\rightarrow$
atoms: LISTofATOM
Errors: [WINDOW]
This request returns the atoms of properties currently defined on window.

## LookupColor

```
    cmap: COLORMAP
    name: STRING8
->
    exact-red, exact-green, exact-blue: CARD16
    visual-red,visual-green, visual-blue: CARD16
Errors: [COLORMAP], [NAME]
```

This request looks up the string name of a color with respect to the screen associated with cmap and returns both the exact color values and the closest values provided by the hardware with respect to the visual type of cmap.
name is compared, case-insensitively, to the valid color names. If name does not use the ISO Latin- 1 encoding, the results are implementation-dependent.

## MapWindow

window: WINDOW
Errors: [WINDOW]
If window is already mapped, this request has no effect.
If the override-redirect attribute of window is False and some other client has selected SubstructureRedirect on the parent, then a MapRequest event is generated, but window remains unmapped. Otherwise, window is mapped and a MapNotify event is generated.
If window is now viewable and its contents have been discarded, the window is tiled with its background (if no background is defined, the existing screen contents are not altered), and exposure events may be generated. If a backing store has been maintained while the window was unmapped, no exposure events are generated. If a backing store is now maintained, a fullwindow exposure is always generated. Otherwise, only visible regions may be reported. Similar tiling and exposure take place for any newly viewable inferiors.

## MapSubwindows

## window: WINDOW

Errors: [WINDOW]
This request performs a MapWindow request on all unmapped children of window, in top-tobottom stacking order.

## NoOperation

This request has no parameters and no results, but the length field can be nonzero, which lets the request be any multiple of 4 bytes in length. The server does not interpret the bytes of the request. ${ }^{7}$
7. Application Usage: This request can be used in its minimum 4-byte form as padding where necessary by client libraries that require requests to begin on 64-bit boundaries.

## OpenFont

fid: FONT<br>name: STRING8

Errors: [ALLOC], [IDCHOICE], [NAME]
This request loads the font named name, if necessary, and associates identifier fid with it.
name is case-insensitive. name should use the ISO Latin-1 encoding and should not use the characters \#0x3F (ASCII implementation-dependent.
Fonts are not associated with a particular screen and can be stored as a component of any graphics context.

## PolyArc

```
    drawable: DRAWABLE
    gc: GCONTEXT
    arcs: LISTofARC
Errors: [DRAWABLE], [GCONTEXT], [MATCH]
```

This request draws circular or elliptical arcs. Each arc is specified by a rectangle and two angles. The angles are signed integers in degrees scaled by 64 , with positive indicating counterclockwise motion and negative indicating clockwise motion. The start of the arc is specified by angle1 relative to the three-o'clock position from the center of the rectangle, and the path and extent of the arc is specified by angle2 relative to the start of the arc. If the magnitude of angle2 is greater than 360 degrees, it is truncated to 360 degrees. The $x$ and $y$ coordinates of the rectangle are relative to the origin of the drawable. For an arc specified as $[x, y, w, h, a 1, a 2]$, the origin of the major and minor axes is at $[x+(w / 2), y+(h / 2)]$, and the infinitely thin path describing the entire circle/ellipse intersects the horizontal axis at $[x, y+(h / 2)]$ and $[x+w, y+(h / 2)]$ and intersects the vertical axis at $[x+(w / 2), y]$ and $[x+(w / 2), y+h]$. These coordinates are not necessarily integral; that is, they are not truncated to discrete coordinates.

For a wide line with line-width $l w$, the ideal bounding outlines for filling are given by the two infinitely thin paths consisting of all points whose perpendicular distance from a tangent to the path of the circle/ellipse is equal to $l w / 2$ (which may be a fractional value). When the width and height of the arc are not equal and both are nonzero, then the actual bounding outlines are implementation-dependent. However, the computation of the shape and position of the bounding outlines (relative to the center of the arc) only depends on the width and height of the arc and the line-width.
cap-style is applied the same as for a line corresponding to the tangent of the circle/ellipse at the endpoint. When the angle of an arc face is not an integral multiple of 90 degrees, and the width and height of the arc are both are nonzero, then the shape and position of the cap at that face is implementation-dependent. However, for a Butt cap, the face is defined by a straight line, and the computation of the position (relative to the center of the arc) and the slope of the line only depends on the width and height of the arc and the angle of the arc face. For other cap styles, the computation of the position (relative to the center of the arc) and the shape of the cap only depends on the width and height of the arc, the line-width, the angle of the arc face, and the direction (clockwise or counter-clockwise) of the arc from the endpoint.
join-style is applied the same as for two lines corresponding to the tangents of the circles/ellipses at the join point. When the width and height of both arcs are nonzero, and the angle of either arc face is not an integral multiple of 90 degrees, then the shape of the join is implementationdependent. However, the computation of the shape only depends on the width and height of each arc, line-width, the angles of the two arc faces, the direction (clockwise or counter-
clockwise) of the arcs from the join point, and the relative orientation of the two arc center points.
For an arc specified as $[x, y, w, h, a 1, a 2]$, the angles must be specified in the effectively skewed coordinate system of the ellipse (for a circle, the angles and coordinate systems are identical). The relationship between these angles and angles expressed in the normal coordinate system of the screen is as follows:

$$
\text { skewed-angle }=\operatorname{atan}(\tan (\text { normal-angle }) * w / h)+\text { adjust }
$$

skewed-angle and normal-angle are expressed in radians (rather than in degrees scaled by 64) in the range $[0,2 \pi)$. The atan returns a value in the range $[-\pi / 2, \pi / 2]$. adjust is:
0 For normal-angle in the range $[0, \pi / 2)$.
$\pi \quad$ For normal-angle in the range $[\pi / 2,(3 \pi) / 2)$.
$2 \pi$ For normal-angle in the range $[(3 \pi) / 2,2 \pi)$.
The arcs are drawn in the order listed. If the last point in one arc coincides with the first point in the following arc, the two arcs join correctly. If the first point in the first arc coincides with the last point in the last arc, the two arcs join correctly. For any given arc, no pixel is drawn more than once. If two arcs join correctly and line-width is greater than 0 and the arcs intersect, no pixel is drawn more than once. Otherwise, the intersecting pixels of intersecting arcs are drawn multiple times. Specifying an arc with one endpoint and a clockwise extent draws the same pixels as specifying the other endpoint and an equivalent counterclockwise extent, except as it affects joins.
By specifying one axis to be 0 , a horizontal or vertical line can be drawn.
Angles are computed based solely on the coordinate system, ignoring the aspect ratio.
The following components of $g c$ must be provided: function, plane-mask, line-width, line-style, cap-style, join-style, fill-style, subwindow-mode, clip- $x$-origin, clip- $y$-origin, clip-mask.
The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, dashes.

## PolyFillArc

```
        drawable: DRAWABLE
        gc: GCONTEXT
        arcs: LISTofARC
```

    Errors: [DRAWABLE], [GCONTEXT], [MATCH]
    For each arc, this request fills the region closed by the infinitely thin path described by the specified arc and one or two line segments, depending on arc-mode. For arc-mode=Chord, the single line segment joining the endpoints of the arc is used. For arc-mode=PieSlice, the two line segments joining the endpoints of the arc with the center point are used.

For an arc specified as $[x, y, w, h, a 1, a 2]$, the origin of the major and minor axes is at $[x+(w / 2)$, $y+(h / 2)]$, and the infinitely thin path describing the entire circle/ellipse intersects the horizontal axis at $[x, y+(h / 2)]$ and $[x+w, y+(h / 2)]$ and intersects the vertical axis at $[x+(w / 2), y]$ and $[x+(w / 2), y+h]$. These coordinates are not necessarily integral; that is, they are not truncated to discrete coordinates.
The arc angles are interpreted as specified in the PolyArc request. When the angle of an arc face is not an integral multiple of 90 degrees, then the precise endpoint on the arc is implementationdependent. However, for arc-mode=Chord, the computation of the pair of endpoints (relative to
the center of the arc) only depends on the width and height of the arc and the angles of the two arc faces. For arc-mode=PieSlice, the computation of an endpoint only depends on the angle of the arc face for that endpoint and the ratio of the arc width to arc height.

The arcs are filled in the order listed. For any given arc, no pixel is drawn more than once. If regions intersect, the intersecting pixels are drawn multiple times.
The following components of $g c$ must be provided: function, plane-mask, fill-style, arc-mode, subwindow-mode, clip- $x$-origin, clip- $y$-origin, clip-mask.
The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple- $x$-origin, tile-stipple- $y$-origin.

## PolyFillRectangle

```
drawable: DRAWABLE
gc: GCONTEXT
rectangles: LISTofRECTANGLE
```

Errors: [DRAWABLE], [GCONTEXT], [MATCH]
This request fills the specified rectangles, as if a 4-point FillPoly were specified for each rectangle:

```
[ \(x, y\) ]
[ \(x+\) width,\(y\) ]
[ \(x+\) width, \(y+\) height \(]\)
[ \(x, y+h e i g h t\) ]
```

The x and y coordinates of each rectangle are relative to the origin of drawable and define the upper-left corner of the rectangle.
The rectangles are drawn in the order listed. For any given rectangle, no pixel is drawn more than once. If rectangles intersect, the intersecting pixels are drawn multiple times.

The following components of $g c$ must be provided: function, plane-mask, fill-style, subwindowmode, clip- $x$-origin, clip- $y$-origin, clip-mask.

The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple- $x$-origin, tile-stipple- $y$-origin.

## PolyLine

## drawable: DRAWABLE

$g c:$ GCONTEXT
coordinate-mode: \{Origin, Previous\}
points: LISTofPOINT

## Errors: [DRAWABLE], [GCONTEXT], [MATCH], [VALUE]

This request draws lines between each pair of points (point $[i]$, point $[i+1]$ ). The lines are drawn in the order listed. The lines join correctly at all intermediate points, and if the first and last points coincide, the first and last lines also join correctly.
For any given line, no pixel is drawn more than once. If thin (0 line-width) lines intersect, the intersecting pixels are drawn multiple times. If wide lines intersect, the intersecting pixels are drawn only once, as though the entire PolyLine were a single filled shape.
The first point is always relative to the origin of drawable. The rest are relative either to that origin or the previous point, depending on coordinate-mode.

When either of the two lines involved in a Bevel join are neither vertical nor horizontal, then the slope and position of the line segment defining the bevel join edge is implementation-dependent. However, the computation of the slope and distance (relative to the join point) only depends on the line width and the slopes of the two lines.

The following components of gc must be provided: function, plane-mask, line-width, line-style, cap-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, clip-mask.
The following mode-dependent components of gc must be provided: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, dashes.

## PolyPoint

## drawable: DRAWABLE

$g c:$ GCONTEXT
coordinate-mode: \{Origin, Previous\}
points: LISTofPOINT
Errors: [DRAWABLE], [GCONTEXT], [MATCH], [VALUE]
This request combines the foreground pixel in $g c$ with the pixel at each point in drawable. The points are drawn in the order listed.

The first point is always relative to the origin of drawable. The rest are relative either to that origin or the previous point, depending on coordinate-mode.
The following components of $g c$ must be provided: function, plane-mask, foreground, subwindowmode, clip-x-origin, clip-y-origin, clip-mask.

## PolyRectangle

drawable: DRAWABLE
$g c$ : GCONTEXT
rectangles: LISTofRECTANGLE
Errors: [DRAWABLE], [GCONTEXT], [MATCH]
This request draws the outlines of the specified rectangles, as if a five-point PolyLine were specified for each rectangle:

$$
[x, y][x+\text { width }, y][x+\text { width }, y+h e i g h t][x, y+h e i g h t][x, y]
$$

The x and y coordinates of each rectangle are relative to the drawable's origin and define the upper-left corner of the rectangle.
The rectangles are drawn in the order listed. For any given rectangle, no pixel is drawn more than once. If rectangles intersect, the intersecting pixels are drawn multiple times.
The following components of gc must be provided: function, plane-mask, line-width, line-style, cap-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip- $y$-origin, clip-mask.

The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple- $y$-origin, dash-offset, dashes.

## PolySegment

drawable: DRAWABLE
$g c:$ GCONTEXT
segments: LISTofSEGMENT
where:
SEGMENT: $[x 1, y 1, x 2, y 2$ : INT16]

## Errors: [DRAWABLE], [GCONTEXT], [MATCH]

For each segment, this request draws a line between $[x 1, y 1]$ and $[x 2, y 2]$. The lines are drawn in the order listed. No joining is performed at coincident endpoints. For any given line, no pixel is drawn more than once. If lines intersect, the intersecting pixels are drawn multiple times.
The following components of $g c$ must be provided: function, plane-mask, line-width, line-style, cap-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, clip-mask.
The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, dashes.

## PolyText8

```
    drawable: DRAWABLE
    gc: GCONTEXT
    x,y: INT16
    items: LISTofTEXTITEM8
    Errors: [DRAWABLE], [FONT], [GCONTEXT], [MATCH]
```

The x and y coordinates are relative to the origin of drawable and specify the baseline starting position (the initial character origin). Each text item is processed in turn. A FONT item causes the font to be stored in $g c$ and to be used for subsequent text. Switching among fonts does not affect the next character origin. A text element delta specifies an additional change in the position along the $x$ axis before the string is drawn; the delta is always added to the character origin. Each character image, as defined by the font in $g c$, is treated as an additional mask for a fill operation on drawable.

All contained FONTs are always transmitted most-significant byte first.
If a [FONT] error is generated for an item, the previous items may have been drawn.
For fonts defined with 2-byte matrix indexing, each STRING8 byte is interpreted as a byte2 value of a CHAR2B with a byte 1 value of 0 .
The following components of gc must be provided: function, plane-mask, fill-style, font, subwindow-mode, clip-x-origin, clip-y-origin, clip-mask.

The following mode-dependent components of $g c$ must be provided: foreground, background, tile, stipple, tile-stipple- $x$-origin, tile-stipple- $y$-origin.

## PolyText16

drawable: DRAWABLE
$g c:$ GCONTEXT
$x, y$ : INT16
items: LISTofTEXTITEM16

## Errors: [DRAWABLE], [FONT], [GCONTEXT], [MATCH]

This request is similar to PolyText8, except 2-byte characters are used. For fonts defined with linear indexing rather than 2-byte matrix indexing, the server interprets each CHAR2B as a 16-bit number that has been transmitted most-significant byte first.

## PutImage

```
drawable: DRAWABLE
\(g c\) : GCONTEXT
depth: CARD8
width, height: CARD16
dst-x, dst-y: INT16
left-pad: CARD8
format: \{Bitmap, XYPixmap, ZPixmap \(\}\)
data: LISTofBYTE
```

## Errors: [DRAWABLE], [GCONTEXT], [MATCH], [VALUE]

This request combines an image with a rectangle of drawable. The $d s t-x$ and $d s t-y$ coordinates are relative to the origin of drawable.
If Bitmap format is used, then depth must be one, or a [MATCH] error results; and the image must be in XY format. The foreground pixel in $g c$ defines the source for bits set to 1 in the image, and the background pixel defines the source for the bits set to 0 .
For XYPixmap and ZPixmap, depth must match the depth of drawable, or a [MATCH] error results. For XYPixmap, the image must be sent in XY format. For ZPixmap, the image must be sent in the Z format defined for depth.
left-pad must be 0 for ZPixmap format, or a [MATCH] error results. For Bitmap and XYPixmap format, left-pad must be less than bitmap-scanline-pad as given in the server connection setup information, or a [MATCH] error results. The server ignores the first left-pad bits in every scanline. The actual image begins that many bits into the data. The width parameter defines the width of the actual image and does not include left-pad.
The following components of $g c$ must be provided: function, plane-mask, subwindow-mode, clip-xorigin, clip-y-origin, clip-mask.
The following mode-dependent components of $g c$ must be provided: foreground, background.

## QueryBestSize

```
    class: {Cursor, Tile, Stipple}
    drawable: DRAWABLE
    width,height: CARD16
->
    width, height: CARD16
    Errors: [DRAWABLE], [MATCH], [VALUE]
```

This request returns the best size that is closest to the parameter size. For Cursor, this is the largest size that can be fully displayed. For Tile, this is the size that can be tiled fastest. For Stipple, this is the size that can be stippled fastest.

For Cursor, drawable indicates the desired screen. For Tile and Stipple, drawable indicates the screen and also possibly the window class and depth. An InputOnly window cannot be used as drawable for Tile or Stipple, or a [MATCH] error results.

## QueryColors

```
    cmap: COLORMAP
    pixels: LISTofCARD32
->
    colors: LISTofRGB
```

where:
RGB: [red, green, blue: CARD16]
Errors: [COLORMAP], [VALUE]
This request returns the implementation-dependent color values stored in cmap for pixels. The values returned for an unallocated entry are unspecified. A [VALUE] error is generated if a pixel is not a valid index into cmap. If more than one pixel is in error, it is unspecified which pixel is reported.

## QueryExtension

```
    name: STRING8
\(\rightarrow\)
    present: BOOL
    major-opcode: CARD8
    first-event: CARD8
    first-error: CARD8
```

This request determines whether the X Window System extension named name is present. If so, the major opcode for the extension is returned, if it has one. Otherwise, 0 is returned. Any minor opcode and the request formats are specific to the extension. If the extension involves additional event types, the base event type code is returned. Otherwise, 0 is returned. The format of the events is specific to the extension. If the extension involves additional error codes, the base error code is returned. Otherwise, 0 is returned. The format of additional data in the errors is specific to the extension.
name is compared case-sensitively to the valid extension names. If name does not use the ISO Latin- 1 encoding, the results are implementation-dependent.

## QueryFont

```
font: FONTABLE
\(\rightarrow\)
font-info: FONTINFO char-infos: LISTofCHARINFO
```

where:
FONTINFO: [draw-direction: \{LeftToRight, RightToLeft\}
min-char-or-byte2, max-char-or-byte2: CARD16
min-byte1, max-byte1: CARD8
all-chars-exist: BOOL
default-char: CARD16
min-bounds: CHARINFO
max-bounds: CHARINFO
font-ascent: INT16
font-descent: INT16
properties: LISTofFONTPROP]
FONTPROP: [name: ATOM
value: <32-bit-value>]
CHARINFO: [left-side-bearing: INT16
right-side-bearing: INT16
character-width: INT16
ascent: INT16
descent: INT16
attributes: CARD16]

## Errors: [FONT]

This request returns logical information about font. If a graphics context is given for font, the currently contained font is used.
draw-direction is a hint and indicates whether most char-infos have a positive, LeftToRight, or a negative, RightToLeft, character-width metric.
If min-byte1 and max-byte1 are both 0 , then min-char-or-byte2 specifies the linear character index corresponding to the first element of char-infos, and max-char-or-byte2 specifies the linear character index of the last element. If either min-byte1 or max-byte1 are nonzero, then both min-char-or-byte2 and max-char-or-byte2 are less than 256, and the 2-byte character index values corresponding to char-infos element N (counting from 0 ) are:

$$
\begin{aligned}
& \text { byte1 }=\mathrm{N} / d+\text { min-byte } 1 \\
& \text { byte2 }=\mathrm{N} \% d+\text { min-char-or-byte } 2
\end{aligned}
$$

where:

$$
\begin{aligned}
& d=\text { max-char-or-byte } 2-\text { min-char-or-byte } 2+1 \\
& /=\text { integer division } \\
& \%=\text { integer modulus }
\end{aligned}
$$

If char-infos has length 0 , then min-bounds and max-bounds are identical, and the effective length of char-infos is:

$$
\mathrm{L}=d^{*}(\text { max-byte } 1-\text { min-byte1 }+1)
$$

That is, all glyphs in the specified linear or matrix range have the same information, as given by min-bounds (and max-bounds). If all-chars-exist is True, then all glyphs in char-infos have nonzero
bounding boxes.
default-char specifies the character used for characters which are not defined or are nonexistent. This is a CARD16, not CHAR2B. For a font using 2-byte matrix format, default-char has byte1 in the most-significant byte and byte2 in the least-significant byte. If default-char itself specifies a character which is not defined or is nonexistent, then no printing is performed.
min-bounds and max-bounds contain the minimum and maximum values of each individual CHARINFO component over all char-infos (ignoring nonexistent characters). The bounding box of the font (that is, the smallest rectangle enclosing the shape obtained by superimposing all glyphs at the same origin $[x, y]$ ) has its upper-left coordinate at:
[ $x+$ min-bounds.left-side-bearing, $y$-max-bounds.ascent]
with a width of:
max-bounds.right-side-bearing-min-bounds.left-side-bearing
and a height of:
max-bounds.ascent+max-bounds.descent
font-ascent is the logical extent of the font above the baseline and is used for determining line spacing. Specific glyphs may extend beyond this. font-descent is the logical extent of the font at or below the baseline and is used for determining line spacing. Specific glyphs may extend beyond this. If the baseline is at $y$-coordinate $y$, then the logical extent of the font is inclusive between the y -coordinate values ( $y$-font-ascent) and ( $y+$ font-descent- 1 ).
A font is not guaranteed to have any properties. The interpretation of the property value (for example, INT32, CARD32) must be derived from a priori knowledge of the property. A basic set of font properties is specified in the XLFD specification (included in the X Window System (X11R6): Fonts and Text Technical Standard).
For a glyph origin at $[x, y]$, the bounding box of a glyph (that is, the smallest rectangle enclosing the glyph's shape), described in terms of CHARINFO components, is a rectangle with its upperleft corner at:
[ $x+$ left-side-bearing, $y$-ascent $]$
with a width of:
right-side-bearing-left-side-bearing
and a height of:
ascent+descent
and the origin for the next glyph is defined to be:
[ $x+$ character-width, $y$ ]
The baseline is logically viewed as being just below non-descending glyphs (when descent is 0 , only pixels with $y$-coordinates less than $y$ are drawn) and that the origin is logically viewed as being coincident with the left edge of a non-kerned glyph (when left-side-bearing is 0 , no pixels with $x$-coordinate less than $x$ are drawn).
CHARINFO metric values can be negative.
A nonexistent character is represented with all CHARINFO components 0 .
The interpretation of the per-character attributes field is implementation-dependent.

## QueryKeymap

$\rightarrow$
keys: LISTofCARD8
This request returns a bit vector for the logical state of the keyboard. Each bit set to 1 indicates that the corresponding key is currently pressed. The vector is represented as 32 bytes. Byte N (from 0 ) contains the bits for keys 8 N to $8 \mathrm{~N}+7$ with the least-significant bit in the byte representing key 8 N . The logical state of a device (as seen by means of the protocol) may lag the physical state if device event processing is frozen.

## QueryPointer

window: WINDOW
$\rightarrow$
root: WINDOW
child: WINDOW or None
same-screen: BOOL
root- $x$, root- $y$, win- $x$, win- $y$ : INT16
mask: SETofKEYBUTMASK
Errors: [WINDOW]
The root window the pointer is logically on and the pointer coordinates relative to the root's origin are returned. If same-screen is False, then the pointer is not on the same screen as the parameter window, child is None, and win- $x$ and win- $y$ are 0 . If same-screen is True, then win- $x$ and win- $y$ are the pointer coordinates relative to the parameter window's origin, and child is the child containing the pointer, if any. The current logical state of the modifier keys and the buttons are also returned. The logical state of a device (as seen by means of the protocol) may lag the physical state if device event processing is frozen.

## QueryTextExtents

```
    font:FONTABLE
    string:STRING16
->
    draw-direction: {LeftToRight,RightToLeft}
    font-ascent: INT16
    font-descent: INT16
    overall-ascent: INT16
    overall-descent: INT16
    overall-width: INT32
    overall-left: INT32
    overall-right: INT32
```

## Errors: [FONT]

This request returns the logical extents of string when rendered in font. If a graphics context is given for font, the currently contained font is used. draw-direction, font-ascent, and font-descent are as described in QueryFont. overall-ascent is the maximum of the ascent metrics of all characters in the string, and overall-descent is the maximum of the descent metrics. overall-width is the sum of the character-width metrics of all characters in the string. For each character in the string, let W be the sum of the character-width metrics of all characters preceding it in the string, let L be the left-side-bearing metric of the character plus W , and let R be the right-side-bearing metric of the character plus W. overall-left is the minimum L of all characters in the string, and overall-right is the maximum R.

For fonts defined with linear indexing rather than 2-byte matrix indexing, the server interprets each CHAR2B as a 16 -bit number that has been transmitted most-significant byte first.
Characters with all 0 metrics are ignored. If the font has no defined default-char, then characters in the string which are not defined are also ignored.

## QueryTree

```
    window: WINDOW
->
    root: WINDOW
    parent: WINDOW or None
    children: LISTofWINDOW
```

Errors: [WINDOW]
This request returns the root, the parent, and the children of window. The children are listed in bottom-to-top stacking order.

## RecolorCursor

cursor: CURSOR<br>fore-red, fore-green, fore-blue: CARD16<br>back-red, back-green, back-blue: CARD16<br>Errors: [CURSOR]

This request changes the color of cursor. If cursor is being displayed on a screen, the change is visible immediately.

## ReparentWindow

window, parent: WINDOW
$x, y$ : INT16
Errors: [MATCH], [WINDOW]
If window is mapped, an UnmapWindow request is performed automatically first. window is then removed from its current position in the hierarchy and is inserted as a child of parent. The $x$ and $y$ coordinates are relative to the origin of parent and specify the new position of the upper-left outer corner of window. window is placed on top in the stacking order with respect to siblings. A ReparentNotify event is then generated. The override-redirect attribute of window is passed on in this event; a value of True indicates that a window manager should not tamper with this window. Finally, if window was originally mapped, a MapWindow request is performed automatically.
Normal exposure processing on formerly obscured windows is performed. The server might not generate exposure events for regions from the initial unmap that are immediately obscured by the final map.
A [MATCH] error is generated if:

- parent is not on the same screen as the old parent.
- parent is window itself or an inferior of window.
- parent is InputOnly and window is not.
- window has a ParentRelative background, and parent is not the same depth as window.

## RotateProperties

window: WINDOW<br>delta: INT16<br>properties: LISTofATOM<br>Errors: [ATOM], [MATCH], [WINDOW]

If the property names in the list are viewed as being numbered starting from 0 , and there are N property names in the list, then the value associated with property name I becomes the value associated with property name ( $\mathrm{I}+$ delta $) \bmod \mathrm{N}$, for all I from 0 to $\mathrm{N}-1$. The effect is to rotate the states by delta places around the virtual ring of property names (right for positive delta, left for negative delta).
If delta mod N is nonzero, a PropertyNotify event is generated for each property in the order listed.

If an atom occurs more than once in the list or no property with that name is defined for the window, a [MATCH] error is generated. If an [ATOM] or [MATCH] error is generated, no properties are changed.

## SendEvent

destination: WINDOW or PointerWindow or InputFocus
propagate: BOOL
event-mask: SETofEVENT
event: 32-byte standard event format
Errors: [VALUE], [WINDOW]
If PointerWindow is specified, destination is replaced with the window that the pointer is in. If InputFocus is specified and the focus window contains the pointer, destination is replaced with the window that the pointer is in. Otherwise, destination is replaced with the focus window.

If event-mask is the empty set, then event is sent to the client that created the destination window. If that client no longer exists, no event is sent.

If propagate is False, then event is sent to every client selecting on destination any of the event types in event-mask.
If propagate is True and no clients have selected on destination any of the event types in event-mask, then destination is replaced with the closest ancestor of destination for which some client has selected a type in event-mask and no intervening window has that type in its do-not-propagatemask. If no such window exists or if the window is an ancestor of the focus window and InputFocus was originally specified as destination, then event is not sent to any clients. Otherwise, event is reported to every client selecting on the final destination any of the types specified in event-mask.

The event code must be one of the core events or one of the events defined by an extension, or a [VALUE] error results, so that the server can correctly byte-swap the contents as necessary. The contents of the event are otherwise unaltered and unchecked by the server except to force on the most-significant bit of the event code and to set the sequence number in the event correctly.

Active grabs are ignored for this request.

## SetAccessControl

mode: \{Enable, Disable\}
Errors: [ACCESS], [VALUE]
This request enables or disables the use of the access control list at connection setups.
The client must have been granted permission by a implementation-dependent method to execute this request, or an [ACCESS] error results.

## SetClipRectangles

$g c:$ GCONTEXT
clip-x-origin, clip-y-origin: INT16
rectangles: LISTofRECTANGLE
ordering: $\{$ UnSorted,,$~ Y$ Sorted, $Y$ YSorted,,$~ Y X B a n d e d\}$
Errors: [ALLOC], [GCONTEXT], [MATCH], [VALUE]
This request changes clip-mask in $g c$ to the specified list of rectangles and sets the clip origin. Output is clipped to remain contained within the rectangles. The clip origin is interpreted relative to the origin of whatever destination drawable is specified in a graphics request. The rectangle coordinates are interpreted relative to the clip origin. The rectangles should be nonintersecting, or graphics results are unspecified. The list of rectangles can be empty, which effectively disables output. This is the opposite of passing None as clip-mask in CreateGC and ChangeGC.
If the client specifies ordering relations on the rectangles with ordering, it may provide faster operation by the server. If an incorrect ordering is specified, the server may generate a [MATCH] error; if no error is generated, the graphics results are unspecified. UnSorted means that the rectangles are in unspecified order. YSorted means that the rectangles are non-decreasing in their Y origin. YXSorted additionally constrains $Y$ Sorted order in that all rectangles with an equal $Y$ origin are non-decreasing in their X origin. YXBanded additionally constrains YXSorted by requiring that, for every possible Y scanline, all rectangles that include that scanline have identical Y origins and Y extents.

## SetCloseDownMode

mode: \{Destroy, RetainPermanent, RetainTemporary\}
Errors: [VALUE]
This request defines what happens to the client's resources at connection close. A connection starts in Destroy mode.

## SetDashes

```
gc: GCONTEXT
dash-offset: CARD16
dashes: LISTofCARD8
```

Errors: [ALLOC], [GCONTEXT], [VALUE]
This request sets dash-offset and dashes in $g c$ for dashed line styles. dashes cannot be empty, or a [VALUE] error results. Specifying an odd-length list is equivalent to specifying the same list concatenated with itself to produce an even-length list. The initial and alternating elements of dashes are the even dashes; the others are the odd dashes. Each element specifies a dash length in pixels. All of the elements must be nonzero or a [VALUE] error results. dash-offset specifies
how many pixels into dashes the pattern begins in any single graphics request. Dashing is continuous through path elements combined with a join-style but is reset to dash-offset between each sequence of joined lines.
The unit of measure for dashes is the same for the ordinary coordinate system for horizontal and vertical lines; for other lines, it is unspecified.

For any graphics primitive, the computation of the endpoint of an individual dash only depends on the geometry of the primitive, the start position of the dash, the direction of the dash, and the dash length.
For any graphics primitive, the total set of pixels used to render the primitive (both even and odd numbered dash elements) with line-style=DoubleDash is the same as the set of pixels used to render the primitive with line-style=Solid.
For any graphics primitive, if the primitive is drawn with OnOffDash or DoubleDash line-style unclipped at position $[x, y]$ and again at position $[x+d x, y+d y]$, then a point $[x 1, y 1]$ is included in a dash in the first instance if and only if the point $[x 1+d x, y 1+d y]$ is included in the dash in the second instance. In addition, the effective set of points comprising a dash cannot be affected by clipping. A point is included in a clipped dash if and only if the point lies inside the clipping region and the point would be included in the dash when drawn unclipped.

## SetFontPath

## path: LISTofSTRING8

## Errors: [VALUE]

This request defines the search path for font lookup. There is only one search path per server, not one per client. The interpretation of the strings is implementation-dependent, but the strings are intended to specify directories to be searched in the order listed.

Setting path to the empty list restores the default path defined for the server.
The server flushes all cached information about fonts that have no explicit resource IDs allocated.

The meaning of an error from this request is implementation-dependent.

## SetInputFocus

focus: WINDOW or PointerRoot or None
revert-to: \{Parent, PointerRoot, None\}
time: TIMESTAMP or CurrentTime

## Errors: [MATCH], [VALUE], [WINDOW]

This request changes the input focus and the last-focus-change time. The request has no effect if time is earlier than the current last-focus-change time or is later than the current server time. Otherwise, the last-focus-change time is set to time with CurrentTime replaced by the current server time.
If None is specified as focus, all keyboard events are discarded until a new focus window is set. In this case, revert-to is ignored.
If a window is specified as the focus, it becomes the keyboard's focus window. If a generated keyboard event would normally be reported to this window or one of its inferiors, the event is reported normally. Otherwise, the event is reported with respect to the focus window.

If PointerRoot is specified as the focus, the focus window is dynamically taken to be the root window of whatever screen the pointer is on at each keyboard event. In this case, revert-to is ignored.
This request generates FocusIn and FocusOut events.
focus must be viewable at the time of the request, or a [MATCH] error results. If the focus window later becomes unviewable, the new focus window depends on revert-to. If revert-to is Parent, the focus reverts to the parent (or the closest viewable ancestor) and the new revert-to value is taken to be None. If revert-to is PointerRoot or None, the focus reverts to that value. When the focus reverts, FocusIn and FocusOut events are generated, but the last-focus-change time is not affected.

## SetModifierMapping

keycodes-per-modifier: CARD8
keycodes: LISTofKEYCODE
$\rightarrow$
status: \{Success, Busy ,Failed\}
Errors: [ALLOC], [VALUE]
This request specifies the keycodes (if any) of the keys to be used as modifiers. The number of keycodes in the list must be $8^{*}$ keycodes-per-modifier, or a [LENGTH] error results. The keycodes are divided into eight sets, with each set containing keycodes-per-modifier elements. The sets are assigned to the modifiers Shift, Lock, Control, Mod1, Mod2, Mod3, Mod4, and Mod5, in order. Only nonzero keycode values are used within each set; 0 values are ignored. All of the nonzero keycodes must be in the range specified by min-keycode and max-keycode in the connection setup, or a [VALUE] error results. The order of keycodes within a set does not matter. If no nonzero values are specified in a set, the use of the corresponding modifier is disabled, and the modifier bit is always 0 . Otherwise, the modifier bit is 1 whenever at least one of the keys in the corresponding set is in the down position.

There may be implementation-dependent restrictions on how modifiers can be changed (for example, if certain keys do not generate up transitions in hardware, if auto-repeat cannot be disabled on certain keys, or if multiple keys per modifier are not supported). The status reply is Failed if some such restriction is violated, and no modifier is changed.

If the new nonzero keycodes specified for a modifier differ from those currently defined and any (current or new) keys for that modifier are logically in the down state, then the status reply is Busy, and none of the modifiers is changed.
This request generates a MappingNotify event on a Success status.

## SetPointerMapping

map: LISTofCARD8
$\rightarrow$
status: \{Success, Busy\}
Errors: [VALUE]
This request sets the mapping of the pointer. Elements of the list are indexed starting from one. The length of the list must be the same as GetPointerMapping would return, or a [VALUE] error results. The index is a core button number, and the element of the list defines the effective number.

A 0 element disables a button. Elements are not restricted in value by the number of physical buttons, but no two elements can have the same nonzero value, or a [VALUE] error results.

If any of the buttons to be altered are logically in the down state, the status reply is Busy, and the mapping is not changed.

This request generates a MappingNotify event on a Success status.

## SetScreenSaver

```
timeout, interval: INT16
prefer-blanking: {Yes, No,Default}
allow-exposures: {Yes,No,Default}
Errors: [VALUE]
```

timeout and interval are specified in seconds; setting a value to -1 restores the default. Other negative values generate a [VALUE] error. If timeout is 0 , the screen-saver is disabled (but an activated screen-saver is not deactivated). If timeout is nonzero, the screen-saver is enabled. Once the screen-saver is enabled, if no input from the keyboard or pointer is generated for timeout seconds, the screen-saver is activated. For each screen, if blanking is preferred and the hardware supports video blanking, the screen goes blank. Otherwise, if either exposures are allowed or the screen can be regenerated without sending exposure events to clients, the screen is changed in an implementation-dependent fashion. Otherwise, the state of the screens does not change, and screen-saver is not activated. At the next keyboard or pointer input or at the next ForceScreenSaver with mode Reset, screen-saver is deactivated, and all screen states are restored. ${ }^{8}$

## SetSelectionOwner

selection: ATOM<br>owner: WINDOW or None<br>time: TIMESTAMP or CurrentTime<br>Errors: [ATOM], [WINDOW]

This request changes the owner, owner window, and last-change-time of selection. This request has no effect if time is earlier than the current last-change-time of selection or is later than the current server time. Otherwise, the last-change-time is set to time with CurrentTime replaced by the current server time. If owner is None, then the owner of the selection becomes None. Otherwise, the owner of the selection becomes the client executing the request. If the new owner (whether a client or None) is not the same as the current owner and the current owner is not None, then the current owner is sent a SelectionClear event.
If the client that is the owner of a selection is later terminated, or if the owner window it has specified in the request is later destroyed, then the owner of the selection automatically reverts to None, but the last-change-time is not affected.

The selection atom is uninterpreted by the server. The owner window is returned by the GetSelectionOwner request and is reported in SelectionRequest and SelectionClear events.
8. Application Usage: If the implementation-dependent screen-saver method supports periodic change, interval serves as a hint on how long the change period should be. 0 hints that no periodic change should be made. Examples of periodic changes to the screen include scrambling the colormap, moving an icon image about the screen, or tiling the screen with the root window background tile with a changed origin.

Selections are global to the server.

## StoreColors

```
cmap: COLORMAP
```

items: LISTofCOLORITEM
Errors: [ACCESS], [COLORMAP], [VALUE]
This request changes the colormap entries of the specified pixels. The do-red, do-green, and do-blue fields indicate which components should change. If cmap is an installed map for its screen, the changes are visible immediately.
All specified pixels that are allocated writable in cmap (by any client) are changed, even if one or more pixels produce an error. A [VALUE] error is generated if a specified pixel is not a valid index into cmap, and an [ACCESS] error is generated if a specified pixel is unallocated or is allocated read-only. If more than one pixel is in error, it is unspecified which pixel is reported.

## StoreNamedColor

cmap: COLORMAP
pixel:CARD32
name: STRING8
do-red, do-green, do-blue: BOOL

## Errors: [ACCESS], [COLORMAP], [NAME], [VALUE]

This request looks up the color named name with respect to the screen associated with cmap and then does a StoreColors in cmap. The [ACCESS] and [VALUE] errors are the same as in StoreColors.

If name does not use the ISO Latin-1 encoding, the results are implementation-dependent.

## TranslateCoordinates

src-window, dst-window: WINDOW
src-x, src-y: INT16
$\rightarrow$
same-screen: BOOL
child: WINDOW or None
$d s t-x, d s t-y$ : INT16
Errors: [WINDOW]
The src-x and src-y coordinates are taken relative to the origin of src-window and are returned as $d s t-x$ and $d s t-y$ coordinates relative to the origin of $d s t-w i n d o w$. If same-screen is False, then srcwindow and dst-window are on different screens, and $d s t-x$ and $d s t-y$ are 0 . If the coordinates are contained in a mapped child of $d s t-w i n d o w$, then that child is returned.

## UngrabButton

modifiers: SETofKEYMASK or AnyModifier
button: BUTTON or AnyButton
grab-window: WINDOW
Errors: [VALUE], [WINDOW]
This request releases the passive button/key combination on grab-window if it was grabbed by this client. If modifiers is AnyModifier, it is equivalent to issuing the request for all possible
modifier combinations (including the combination of no modifiers). A button of AnyButton is equivalent to issuing the request for all possible buttons. The request has no effect on an active grab.

## UngrabKey

```
key: KEYCODE or AnyKey
    modifiers: SETofKEYMASK or AnyModifier
    grab-window: WINDOW
```

Errors: [VALUE], [WINDOW]
This request releases the key combination on grab-window if it was grabbed by this client. If modifiers is AnyModifier, it is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). A key of AnyKey is equivalent to issuing the request for all possible keycodes. This request has no effect on an active grab.

## UngrabKeyboard

time: TIMESTAMP or CurrentTime
This request releases the keyboard if this client has it actively grabbed (as a result of either GrabKeyboard or GrabKey) and releases any queued events. The request has no effect if time is earlier than the last-keyboard-grab time or is later than the current server time.
This request generates FocusIn and FocusOut events.
An UngrabKeyboard is performed automatically if the event window for an active keyboard grab becomes unviewable.

## UngrabPointer

## time: TIMESTAMP or CurrentTime

This request releases the pointer if this client has it actively grabbed (from either GrabPointer or GrabButton or from a normal button press) and releases any queued events. The request has no effect if time is earlier than the last-pointer-grab time or is later than the current server time.
This request generates EnterNotify and LeaveNotify events.
An UngrabPointer request is performed automatically if the event window or confine-to window for an active pointer grab becomes unviewable or if window reconfiguration causes the confine-to window to lie completely outside the boundaries of the root window.

## UngrabServer

(No request-specific parameters.)
This request restarts processing of requests and close-downs on other connections.

## UninstallColormap

## cmap: COLORMAP

## Errors: [COLORMAP]

If cmap is on the required list for its screen (see InstallColormap request), it is removed from the list. Also, cmap may be uninstalled, and additional colormaps may be implicitly installed or uninstalled. Which colormaps get installed or uninstalled is implementation-dependent, except that the required list must remain installed.

If cmap becomes uninstalled, a ColormapNotify event is generated on every window having cmap as an attribute. In addition, for every other colormap that is installed or uninstalled as a result of the request, a ColormapNotify event is generated on every window having that colormap as an attribute.

## UnmapSubwindows

## window: WINDOW

Errors: [WINDOW]
This request performs an UnmapWindow request on all mapped children of window, in bottom-to-top stacking order.

## UnmapWindow

window: WINDOW
Errors: [WINDOW]
If the window is already unmapped, this request has no effect. Otherwise, the window is unmapped, and an UnmapNotify event is generated. Normal exposure processing on formerly obscured windows is performed.

## WarpPointer

src-window: WINDOW or None
dst-window: WINDOW or None
src- $x$, src- $y$ : INT16
src-width, src-height: CARD16
$d s t-x, d s t-y$ : INT16
Errors: [WINDOW]
If $d s t-$ window is None, this request moves the pointer by offsets $[d s t-x, d s t-y]$ relative to the current position of the pointer. If dst-window is a window, this request moves the pointer to [dst$x, d s t-y]$ relative to the origin of $d s t-w i n d o w$. However, if src-window is not None, the move only takes place if src-window contains the pointer and the pointer is contained in the specified rectangle of src-window.
The src-x and src-y coordinates are relative to the origin of src-window. If src-height is 0 , it is replaced with the current height of src-window minus $s r c-y$. If $s r c-w i d t h$ is 0 , it is replaced with the current width of src-window minus src-x.
This request cannot be used to move the pointer outside the confine-to window of an active pointer grab. An attempt only moves the pointer as far as the closest edge of the confine-to window.

This request generates events as if the user had instantaneously moved the pointer.

Section 4.1 lists alphabetically each type of core event that a server can send to a client, following the syntactic conventions set out in Section 1.3 on page 3.
Section 4.2 on page 93 specifies the effects when a button is pressed and no active grab is in progress.

### 4.1 Alphabetical List of Events

## ButtonPress, ButtonRelease

```
root, event: WINDOW
child: WINDOW or None
same-screen: BOOL
root-x, root-y, event-x, event-y: INT16
detail: BUTTON
state: SETofKEYBUTMASK
time: TIMESTAMP
```

These events are generated when a button logically changes state. The generation of these logical changes may lag the physical changes if device event processing is frozen. The source of the event is the window the pointer is in. The event window is found by starting with the source window and looking up the hierarchy for the first window on which any client has selected interest in the event (provided no intervening window prohibits event generation by including the event type in its do-not-propagate-mask). The actual window used for reporting can be modified by active grabs and, in the case of keyboard events, can be modified by the focus window.
root is the root window of the source window, and root- $x$ and root- $y$ are the pointer coordinates relative to the root's origin at the time of the event.
If event is on the same screen as root, then event- $x$ and event- $y$ are the pointer coordinates relative to the event window's origin. Otherwise, event- $x$ and event- $y$ are 0 .
If the source window is an inferior of event, then child is set to the child of event that is an ancestor of (or is) the source window. Otherwise, it is set to None. state gives the logical state of the buttons and modifier keys just before the event.

## CirculateNotify

event, window: WINDOW
place: \{Top, Bottom $\}$
This event is reported to clients selecting StructureNotify on the window and to clients selecting SubstructureNotify on the parent. It is generated when the window is actually restacked from a CirculateWindow request. event is the window on which the event was generated, and window is the window that is restacked. If place is Top, the window is now on top of all siblings. Otherwise, it is below all siblings.

## CirculateRequest

parent, window: WINDOW
place: $\{$ Top, Bottom $\}$
This event is reported to the client selecting SubstructureRedirect on parent and is generated when a CirculateWindow request is issued on parent and a window actually needs to be restacked. window specifies the window to be restacked, and place specifies the new position in the stacking order.

## ClientMessage

window: WINDOW
type: ATOM
format: $\{8,16,32\}$
data: LISTofINT8 or LISTofINT16 or LISTofINT32
This event is only generated by clients using SendEvent. type specifies how data is to be interpreted by the receiving client; the server does not interpret type or data. format specifies whether the data should be viewed as a list of 8 -bit, 16 -bit, or 32 -bit quantities, so that the server can correctly byte-swap, as necessary. data consists of either twenty 8 -bit values or ten 16-bit values or five 32-bit values, although particular message types might not make use of all of these values.

## ColormapNotify

window: WINDOW<br>colormap: COLORMAP or None<br>new: BOOL<br>state: $\{$ Installed, Uninstalled $\}$

This event is reported to clients selecting ColormapChange on the window. It is generated with new=True when the colormap attribute of window is changed, and with new=False when the colormap of window is installed or uninstalled. In either case, state indicates whether the colormap is currently installed.

## ConfigureNotify

```
event, window: WINDOW
x,y: INT16
width, height, border-width: CARD16
above-sibling: WINDOW or None
override-redirect: BOOL
```

This event is reported to clients selecting StructureNotify on the window and to clients selecting SubstructureNotify on the parent. It is generated when a ConfigureWindow request actually changes the state of the window. event is the window on which the event was generated, and window is the window that is changed. The $x$ and $y$ coordinates are relative to the new parent's origin and specify the position of the upper-left outer corner of the window. width and height specify the inside size, not including the border. If above-sibling is None, then the window is on the bottom of the stack with respect to siblings. Otherwise, the window is immediately on top of the specified sibling. The override-redirect flag is from the window's attribute.

## ConfigureRequest

parent, window: WINDOW
$x, y$ : INT16
width, height, border-width: CARD16
sibling: WINDOW or None
stack-mode: \{Above, Below, TopIf, BottomIf, Opposite\}
value-mask: BITMASK
This event is reported to the client selecting SubstructureRedirect on the parent and is generated when a ConfigureWindow request is issued on the window by some other client. value-mask indicates the components specified in the request. value-mask and the corresponding values are reported as given in the request. The remaining values are filled in from the current geometry of the window, except in the case of sibling and stack-mode, which are reported as None and Above, respectively, if not given in the request.

## CreateNotify

parent, window: WINDOW
$x, y$ : INT16
width, height, border-width: CARD16
override-redirect: BOOL
This event is reported to clients selecting SubstructureNotify on the parent and is generated when the window is created. The parameters are as in the CreateWindow request.

## DestroyNotify

event, window: WINDOW
This event is reported to clients selecting StructureNotify on the window and to clients selecting SubstructureNotify on the parent. It is generated when the window is destroyed. event is the window on which the event was generated, and window is the window that is destroyed.

The ordering of the DestroyNotify events is such that for any given window, DestroyNotify is generated on all inferiors of the window before being generated on the window itself. The ordering among siblings and across subhierarchies is otherwise unspecified.

## EnterNotify, LeaveNotify

```
root, event: WINDOW
    child: WINDOW or None
    same-screen: BOOL
    root-x, root-y, event-x, event- }y\mathrm{ : INT16
    mode: {Normal, Grab, Ungrab}
    detail: {Ancestor,Virtual,Inferior,Nonlinear,NonlinearVirtual}
    focus: BOOL
    state: SETofKEYBUTMASK
    time: TIMESTAMP
```

If pointer motion or window hierarchy change causes the pointer to be in a different window than before, EnterNotify and LeaveNotify events are generated instead of a MotionNotify event. Only clients selecting EnterWindow on a window receive EnterNotify events, and only clients selecting LeaveWindow receive LeaveNotify events. The pointer position reported in the event is always the final position, not the initial position of the pointer. root is the root window for this position, and root- $x$ and root- $y$ are the pointer coordinates relative to the root's origin at the time of the event. event is the event window. If event is on the same screen as root, then event- $x$ and
event- $y$ are the pointer coordinates relative to the event window's origin. Otherwise, event- $x$ and event- $y$ are 0 . In a LeaveNotify event, if a child of the event window contains the initial position of the pointer, then child is set to that child. Otherwise, it is None. For an EnterNotify event, if a child of the event window contains the final pointer position, then child is set to that child. Otherwise, it is None. If event is the focus window or an inferior of the focus window, then focus is True; otherwise, focus is False.

Normal pointer motion events have mode=Normal. Pseudo-motion events when a grab activates have mode=Grab, and pseudo-motion events when a grab deactivates have mode=Ungrab.
All EnterNotify and LeaveNotify events caused by a hierarchy change are generated after any hierarchy event caused by that change (that is, UnmapNotify, MapNotify, ConfigureNotify, GravityNotify, CirculateNotify), but the ordering of EnterNotify and LeaveNotify events with respect to FocusOut, VisibilityNotify, and Expose events is unspecified.
Normal events are generated as follows.
When the pointer moves from window $A$ to window $B$ and $A$ is an inferior of $B$ :

- LeaveNotify with detail=Ancestor is generated on A.
- LeaveNotify with detail=Virtual is generated on each window between A and B exclusive (in order).
- EnterNotify with detail=Inferior is generated on B.

When the pointer moves from window $A$ to window $B$ and $B$ is an inferior of $A$ :

- LeaveNotify with detail=Inferior is generated on A.
- EnterNotify with detail=Virtual is generated on each window between A and B exclusive (in order).
- EnterNotify with detail=Ancestor is generated on B.

When the pointer moves from window A to window B and window C is their closest common ancestor:

- LeaveNotify with detail=Nonlinear is generated on A.
- LeaveNotify with detail=NonlinearVirtual is generated on each window between A and C exclusive (in order).
- EnterNotify with detail=NonlinearVirtual is generated on each window between C and B exclusive (in order).
- EnterNotify with detail=Nonlinear is generated on B.

When the pointer moves from window A to window B on different screens:

- LeaveNotify with detail=Nonlinear is generated on A.
- If A is not a root window, LeaveNotify with detail=NonlinearVirtual is generated on each window above A up to and including its root (in order).
- If B is not a root window, EnterNotify with detail=NonlinearVirtual is generated on each window from B's root down to but not including B (in order).
- EnterNotify with detail=Nonlinear is generated on B.

When a pointer grab activates (but after any initial warp into a confine-to window and before generating any actual ButtonPress event that activates the grab), G is the grab-window for the grab, and $P$ is the window the pointer is in:

- EnterNotify and LeaveNotify events with mode Grab are generated (as for Normal above) as if the pointer were to suddenly warp from its current position in P to some position in G . However, the pointer does not warp, and the pointer position is used as both the initial and final positions for the events.

When a pointer grab deactivates (but after generating any actual ButtonRelease event that deactivates the grab), $G$ is the grab-window for the grab, and $P$ is the window the pointer is in:

- EnterNotify and LeaveNotify events with mode=Ungrab are generated (as for Normal above) as if the pointer were to suddenly warp from some position in $G$ to its current position in $P$. However, the pointer does not warp, and the current pointer position is used as both the initial and final positions for the events.

## Expose

window: WINDOW
$x, y$, width, height: CARD16
count: CARD16
This event is reported to clients selecting Expose on the window. It is generated when no valid contents are available for regions of a window, and either the regions are visible, the regions are viewable and the server is (perhaps newly) maintaining backing store on the window, or the window is not viewable but the server is (perhaps newly) honoring the window's backing-store attribute of Always or WhenMapped. The regions are decomposed into an unspecified set of rectangles, and an Expose event is generated for each rectangle.
For a given action causing exposure events, the set of events for a given window is guaranteed to be reported contiguously.
If count is 0 , then no more Expose events for this window follow. If count is nonzero, then at least that many more Expose events for this window follow.

The $x$ and $y$ coordinates are relative to window's origin and specify the upper-left corner of a rectangle. width and height specify the extent of the rectangle.

Expose events are never generated on InputOnly windows.
All Expose events caused by a hierarchy change are generated after any hierarchy event caused by that change (for example, UnmapNotify, MapNotify, ConfigureNotify, GravityNotify, CirculateNotify). All Expose events on a given window are generated after any VisibilityNotify event on that window, but it is not required that all Expose events on all windows be generated after all Visibility events on all windows.
The ordering of Expose events with respect to FocusOut, EnterNotify, and LeaveNotify events is unspecified.

## FocusIn, FocusOut

event: WINDOW
mode: \{Normal, WhileGrabbed, Grab, Ungrab\}
detail: \{Ancestor, Virtual, Inferior, Nonlinear, NonlinearVirtual, Pointer, PointerRoot, None\}
These events are generated when the input focus changes and are reported to clients selecting FocusChange on the window. Events generated by SetInputFocus when the keyboard is not grabbed have mode=Normal. Events generated by SetInputFocus when the keyboard is grabbed have mode=WhileGrabbed. Events generated when a keyboard grab activates have mode=Grab, and events generated when a keyboard grab deactivates have mode=Ungrab.

All FocusOut events caused by a window unmap are generated after any UnmapNotify event, but the ordering of FocusOut with respect to generated EnterNotify, LeaveNotify, VisibilityNotify, and Expose events is unspecified.
Normal and WhileGrabbed events are generated as follows.
When the focus moves from window $A$ to window $B, A$ is an inferior of $B$, and the pointer is in window P:

- FocusOut with detail=Ancestor is generated on A.
- FocusOut with detail=Virtual is generated on each window between A and B exclusive (in order).
- FocusIn with detail=Inferior is generated on B.
- If $P$ is an inferior of $B$ but $P$ is not $A$ or an inferior of $A$ or an ancestor of $A$, FocusIn with detail=Pointer is generated on each window below B down to and including P (in order).

When the focus moves from window $A$ to window $B, B$ is an inferior of $A$, and the pointer is in window P:

- If P is an inferior of A but P is not an inferior of B or an ancestor of B, FocusOut with detail=Pointer is generated on each window from P up to but not including A (in order).
- FocusOut with detail=Inferior is generated on A.
- FocusIn with detail=Virtual is generated on each window between A and B exclusive (in order).
- FocusIn with detail=Ancestor is generated on B.

When the focus moves from window $A$ to window $B$, window $C$ is their closest common ancestor, and the pointer is in window P :

- If P is an inferior of A, FocusOut with detail=Pointer is generated on each window from P up to but not including A (in order).
- FocusOut with detail=Nonlinear is generated on A.
- FocusOut with detail=NonlinearVirtual is generated on each window between A and C exclusive (in order).
- FocusIn with detail=NonlinearVirtual is generated on each window between C and B exclusive (in order).
- FocusIn with detail=Nonlinear is generated on B.
- If P is an inferior of B , FocusIn with detail=Pointer is generated on each window below B down to and including P (in order).

When the focus moves from window A to window B on different screens and the pointer is in window P:

- If P is an inferior of A, FocusOut with detail=Pointer is generated on each window from P up to but not including A (in order).
- FocusOut with detail=Nonlinear is generated on A.
- If A is not a root window, FocusOut with detail=NonlinearVirtual is generated on each window above A up to and including its root (in order).
- If B is not a root window, FocusIn with detail=NonlinearVirtual is generated on each window from B's root down to but not including B (in order).
- FocusIn with detail=Nonlinear is generated on B.
- If P is an inferior of B, FocusIn with detail=Pointer is generated on each window below B down to and including $P$ (in order).

When the focus moves from window A to PointerRoot (or None) and the pointer is in window P:

- If P is an inferior of A, FocusOut with detail=Pointer is generated on each window from P up to but not including A (in order).
- FocusOut with detail=Nonlinear is generated on A.
- If A is not a root window, FocusOut with detail=NonlinearVirtual is generated on each window above A up to and including its root (in order).
- FocusIn with detail=PointerRoot (or None) is generated on all root windows.
- If the new focus is PointerRoot, FocusIn with detail=Pointer is generated on each window from P's root down to and including P (in order).

When the focus moves from PointerRoot (or None) to window A and the pointer is in window P:

- If the old focus is PointerRoot,FocusOut with detail=Pointer is generated on each window from P up to and including P's root (in order).
- FocusOut with detail=PointerRoot (or None) is generated on all root windows.
- If A is not a root window, FocusIn with detail=NonlinearVirtual is generated on each window from A's root down to but not including A (in order).
- FocusIn with detail=Nonlinear is generated on A.
- If P is an inferior of A, FocusIn with detail=Pointer is generated on each window below A down to and including $P$ (in order).
When the focus moves from PointerRoot to None (or vice versa) and the pointer is in window P:
- If the old focus is PointerRoot,FocusOut with detail=Pointer is generated on each window from P up to and including P's root (in order).
- FocusOut with detail=PointerRoot (or None) is generated on all root windows.
- FocusIn with detail=None (or PointerRoot) is generated on all root windows.
- If the new focus is PointerRoot, FocusIn with detail=Pointer is generated on each window from P's root down to and including P (in order).
When a keyboard grab activates (but before generating any actual KeyPress event that activates the grab), G is the grab-window for the grab, and F is the current focus:
- FocusIn and FocusOut events with mode=Grab are generated (as for Normal above) as if the focus were to change from F to G .

When a keyboard grab deactivates (but after generating any actual KeyRelease event that deactivates the grab), G is the grab-window for the grab, and F is the current focus:

- FocusIn and FocusOut events with mode=Ungrab are generated (as for Normal above) as if the focus were to change from $G$ to $F$.

## GraphicsExpose

drawable: DRAWABLE<br>$x, y$, width, height: CARD16<br>count: CARD16<br>major-opcode: CARD8<br>minor-opcode: CARD16

This event is reported to clients selecting graphics-exposures in a graphics context and is generated when a destination region could not be computed due to an obscured or out-ofbounds source region. All of the regions exposed by a given graphics request are reported contiguously. If count is 0 , then no more GraphicsExpose events for this window follow. If count is nonzero, then at least that many more GraphicsExpose events for this window follow.
The $x$ and $y$ coordinates are relative to the drawable's origin and specify the upper-left corner of a rectangle. width and height specify the extent of the rectangle.
major-opcode and minor-opcode identify the graphics request used. For the core protocol, majoropcode is CopyArea or CopyPlane, and minor-opcode is 0.

## GravityNotify

event, window: WINDOW
$x, y$ : INT16
This event is reported to clients selecting SubstructureNotify on the parent and to clients selecting StructureNotify on the window. It is generated when a window is moved because of a change in size of the parent. event is the window on which the event was generated, and window is the window that is moved. The $x$ and $y$ coordinates are relative to the new parent's origin and specify the position of the upper-left outer corner of the window.

## KeymapNotify

keys: LISTofCARD8
The value is a bit vector as described in QueryKeymap. This event is reported to clients selecting KeymapState on a window and is generated immediately after every EnterNotify and FocusIn.

## KeyPress, KeyRelease

root, event: WINDOW
child: WINDOW or None
same-screen: BOOL
root- $x$, root- $y$, event- $x$, event- $y$ : INT16
detail: KEYCODE
state: SETofKEYBUTMASK
time: TIMESTAMP
These events are generated when a key logically changes state. The generation of these logical changes may lag the physical changes if device event processing is frozen. These events are generated for all keys, even those mapped to modifier bits. The source of the event is the window the pointer is in. The event window is found by starting with the source window and looking up the hierarchy for the first window on which any client has selected interest in the event (provided no intervening window prohibits event generation by including the event type in its do-not-propagate-mask). The actual window used for reporting can be modified by active grabs and, in the case of keyboard events, can be modified by the focus window.
root is the root window of the source window, and root- $x$ and root- $y$ are the pointer coordinates relative to the origin of root at the time of the event. If event is on the same screen as root, then event- $x$ and event- $y$ are the pointer coordinates relative to the event window's origin. Otherwise, event- $x$ and event- $y$ are 0 . If the source window is an inferior of the event window, then child is set to the child of the event window that is an ancestor of (or is) the source window. Otherwise, it is set to None. state gives the logical state of the buttons and modifier keys just before the event.

## LeaveNotify

(See EnterNotify.)

## MapNotify

event, window: WINDOW
override-redirect: BOOL
This event is reported to clients selecting StructureNotify on the window and to clients selecting SubstructureNotify on the parent. It is generated when the window changes state from unmapped to mapped. event is the window on which the event was generated, and window is the window that is mapped. override-redirect is from the window's attribute.

## MappingNotify

request: $\{$ Modifier, Keyboard, Pointer\}
first-keycode, count: CARD8
This event is sent to all clients. There is no mechanism to express disinterest in this event. request indicates the kind of change that occurred: Modifiers for a successful SetModifierMapping, Keyboard for a successful ChangeKeyboardMapping, and Pointer for a successful SetPointerMapping. If request=Keyboard, then first-keycode and count indicate the range of altered keycodes.

## MapRequest

parent, window: WINDOW
This event is reported to the client selecting SubstructureRedirect on the parent and is generated when a MapWindow request is issued on an unmapped window with an override-redirect attribute of False.

## MotionNotify

```
root,event: WINDOW
child: WINDOW or None
same-screen: BOOL
root-x, root-y, event-x, event-y: INT16
detail: {Normal, Hint}
state: SETofKEYBUTMASK
time: TIMESTAMP
```

These events are generated when the pointer logically moves. The generation of these logical changes may lag the physical changes if device event processing is frozen. The source of the event is the window the pointer is in. The event window is found by starting with the source window and looking up the hierarchy for the first window on which any client has selected interest in the event (provided no intervening window prohibits event generation by including the event type in its do-not-propagate-mask). The actual window used for reporting can be modified by active grabs and, in the case of keyboard events, can be modified by the focus
window.
root is the root window of the source window, and root- $x$ and root- $y$ are the pointer coordinates relative to root's origin at the time of the event. If event is on the same screen as root, then event- $x$ and event- $y$ are the pointer coordinates relative to the origin of event. Otherwise, event- $x$ and event- $y$ are 0 . If the source window is an inferior of event, then child is set to the child of event that is an ancestor of (or is) the source window. Otherwise, it is set to None. state gives the logical state of the buttons and modifier keys just before the event.

MotionNotify events are only generated when the motion begins and ends in the window. The granularity of motion events is not guaranteed, but a client selecting for motion events is guaranteed to get at least one event when the pointer moves and comes to rest. Selecting PointerMotion receives events independent of the state of the pointer buttons. By selecting some subset of Button[1-5]Motion instead, MotionNotify events are received only when one or more of the specified buttons are pressed. By selecting ButtonMotion, MotionNotify events are received only when at least one button is pressed. The events are always of type MotionNotify, independent of the selection. If PointerMotionHint is selected, the server may send a single MotionNotify event with detail=Hint to the client for the event window until either the key or button state changes, the pointer leaves the event window, or the client issues a QueryPointer or GetMotionEvents request.

## NoExpose

```
drawable: DRAWABLE
major-opcode: CARD8
minor-opcode: CARD16
```

This event is reported to clients selecting graphics-exposures in a graphics context and is generated when a graphics request that might produce GraphicsExpose events does not produce any. drawable specifies the destination used for the graphics request.
major-opcode and minor-opcode identify the graphics request used. For the core X protocol, majoropcode is CopyArea or CopyPlane, and minor-opcode is 0.

## PropertyNotify

window: WINDOW
atom: ATOM
state: $\{$ NewValue, Deleted $\}$
time: TIMESTAMP
This event is reported to clients selecting PropertyChange on window and is generated with state $=$ NewValue when a property of window is changed using ChangeProperty or RotateProperties, even when adding zero-length data using ChangeProperty and when replacing all or part of a property with identical data using ChangeProperty or RotateProperties. It is generated with state=Deleted when a property of window is deleted using request DeleteProperty or GetProperty. time indicates the server time when the property was changed.

## ReparentNotify

event, window, parent: WINDOW
$x, y$ : INT16
override-redirect: BOOL
This event is reported to clients selecting SubstructureNotify on either the old or the new parent, and to clients selecting StructureNotify on the window. It is generated when window is reparented. event is the window on which the event was generated. parent specifies the new parent. The $x$ and $y$ coordinates are relative to the new parent's origin and specify the position of the upper-left outer corner of the window. The override-redirect flag is from the window's attribute.

## ResizeRequest

window: WINDOW
width, height: CARD16
This event is reported to the client selecting ResizeRedirect on window and is generated when a ConfigureWindow request by some other client on window tries to change the size of window. width and height are the inside size, not including the border.

## SelectionClear

```
owner: WINDOW
selection: ATOM
time: TIMESTAMP
```

This event is reported to the current owner of selection and is generated when a new owner is being defined by means of SetSelectionOwner. time is the last-change-time recorded for the selection. owner is the window that was specified by the current owner in its SetSelectionOwner request.

## SelectionNotify

requestor: WINDOW
selection, target: ATOM
property: ATOM or None
time: TIMESTAMP or CurrentTime
This event is generated by the server in response to a ConvertSelection request when there is no owner for the selection. When there is an owner, it should be generated by the owner using SendEvent. The owner of a selection should send this event to a requestor either when a selection has been converted and stored as a property or when a selection conversion could not be performed (indicated with property=None).

## SelectionRequest

owner: WINDOW
selection: ATOM
target: ATOM
property: ATOM or None
requestor: WINDOW
time: TIMESTAMP or CurrentTime
This event is reported to the owner of selection and is generated when a client issues a ConvertSelection request. owner is the window specified in the SetSelectionOwner request. The
remaining parameters are as in the ConvertSelection request.
The owner should convert selection based on the type of target and send a SelectionNotify back to the requestor.

## UnmapNotify

event, window: WINDOW
from-configure: BOOL
This event is reported to clients selecting StructureNotify on window and to clients selecting SubstructureNotify on the parent. It is generated when window changes state from mapped to unmapped. event is the window on which the event was generated, and window is the window that is unmapped. The from-configure flag is True if the event was generated as a result of the window's parent being resized when the window itself had a win-gravity of Unmap.

## VisibilityNotify

```
window: WINDOW
state: \(\{\) Unobscured, PartiallyObscured, FullyObscured \(\}\)
```

This event is reported to clients selecting VisibilityChange on window. In the following, the state of window is calculated ignoring all subwindows. When a window changes state from partially or fully obscured or not viewable to viewable and completely unobscured, an event with Unobscured is generated. When a window changes state from viewable and completely unobscured or not viewable, to viewable and partially obscured, an event with PartiallyObscured is generated. When a window changes state from viewable and completely unobscured, from viewable and partially obscured, or from not viewable to viewable and fully obscured, an event with FullyObscured is generated.

VisibilityNotify events are never generated on InputOnly windows.
All VisibilityNotify events caused by a hierarchy change are generated after any hierarchy event caused by that change (for example, UnmapNotify, MapNotify, ConfigureNotify, GravityNotify, CirculateNotify). Any VisibilityNotify event on a given window is generated before any Expose events on that window, but it is not required that all VisibilityNotify events on all windows be generated before all Expose events on all windows. The ordering of VisibilityNotify events with respect to FocusOut, EnterNotify, and LeaveNotify events is unspecified.

### 4.2 Button-Press Procedure

When a button press is processed with the pointer in some window W and no active pointer grab is in progress, the ancestors of W are searched from the root down, looking for a passive grab to activate. If no matching passive grab on the button exists, then an active grab is started automatically for the client receiving the event, and the last-pointer-grab time is set to the current server time.

The effect of the grab is essentially equivalent to a GrabButton with parameters:

| Parameter | Value |
| :--- | :--- |
| event-window | Event window. |
| event-mask | Client's selected pointer events on the event window. |
| pointer-mode, keyboard-mode | Asynchronous. |
| owner-events | True if the client has OwnerGrabButton selected on the <br> event window, otherwise False. |
| confine-to | None. |
| cursor | None. |

The grab is terminated automatically when the logical state of the pointer has all buttons released. UngrabPointer and ChangeActivePointerGrab can both be used to modify the active grab.

For the syntactic conventions used in this chapter, see Section 1.3.3 on page 3 .

### 5.2 Keyboards and Pointers

KEYCODE values are always greater than 7 (and less than 256).
KEYSYM values with the bit \#0x10000000 set are reserved as implementation-dependent.
The names and encodings of the standard KEYSYM values are contained in Appendix A.
BUTTON values are numbered starting with 1.

### 5.4 Connection Setup

For TCP connections, displays on a given host are numbered starting from 0 , and the server for display N listens and accepts connections on port $6000+\mathrm{N}$.

Information sent by the client at connection setup:

| 1 |  | MSB first | byte-order |
| :--- | :--- | :--- | :--- |
|  | \#0x42 | LSB first |  |
|  | \#0x6C |  | unused |
| 1 |  | protocol-major-version |  |
| 2 | CARD16 | protocol-minor-version |  |
| 2 | CARD16 | length of authorization-protocol-name |  |
| 2 | n | length of authorization-protocol-data |  |
| 2 | d | unused |  |
| 2 |  | authorization-protocol-name |  |
| n | STRING8 | unused, p=pad(n) |  |
| p |  | authorization-protocol-data |  |
| d | STRING8 | unused, q=pad(d) |  |

Except where explicitly noted in the protocol, all 16-bit and 32 -bit quantities sent by the client are transmitted with the specified byte order, and all 16-bit and 32-bit quantities returned by the server are transmitted with this byte order.
Information received by the client if the connection is refused:

| 1 | 0 | Failed |
| :---: | :---: | :---: |
| 1 | n | length of reason in bytes |
| 2 | CARD16 | protocol-major-version |
| 2 | CARD16 | protocol-minor-version |
| 2 | $(\mathrm{n}+\mathrm{p}) / 4$ | length in 4-byte units of "additional data" |
| n | STRING8 | reason |
| p |  | unused, $\mathrm{p}=\mathrm{pad}(\mathrm{n})$ |
| Information received by the client if further authentication is required: |  |  |
| 1 | 2 | Authenticate |
| 5 |  | unused |
| 2 | $(\mathrm{n}+\mathrm{p}) / 4$ | length in 4-byte units of "additional data" |
| n | STRING8 | reason |
| p |  | unused, $\mathrm{p}=\mathrm{pad}(\mathrm{n})$ |

Information received by the client if authorization is accepted:

Protocol Encoding

## KEYSYM Encoding

For convenience, KEYSYM values can be viewed as split into 4 bytes:

- Byte 1 (for the purposes of this encoding) is the most-significant 5 bits (because of the 29-bit effective values).
- Byte 2 is the next most-significant 8 bits.
- Byte 3 is the next most-significant 8 bits.
- Byte 4 is the least-significant 8 bits.

KEYSYMs with the most-significant bit set (of the 29 bits) are reserved as implementationdependent.

There are two special KEYSYM values: NoSymbol and VoidSymbol. They are used to indicate the absence of symbols.

| Byte 1 | Byte 2 | Byte 3 | Byte 4 | Name |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 0 | NoSymbol |
| 0 | 255 | 255 | 255 | VoidSymbol |

All other standard KEYSYM values have bytes 1 and 2 set to 0 . Byte 3 indicates a character code set and byte 4 selects a character within that set.

| Byte 3 | Character Set |
| :--- | :--- |
| 0 | ISO Latin-1 |
| 1 | ISO Latin-2 |
| 2 | ISO Latin-3 |
| 3 | ISO Latin-4 |
| 4 | Kana |
| 5 | Arabic |
| 6 | Cyrillic |
| 7 | Greek |
| 8 | Technical |
| 9 | Special |
| 10 | Publishing |
| 11 | APL |
| 12 | Hebrew |
| 13 | Thai |
| 14 | Korean |
| 15 | ISO Latin-5* |
| 16 | ISO Latin-6* |
| 17 | ISO Latin-7* |
| 18 | ISO Latin-8* |
| 19 | ISO Latin-9* |
| 32 | Currency |

| Byte 3 | Character Set |
| :--- | :--- |
| 255 | Keyboard |

Character sets may contain gaps where codes have been removed that were duplicates with codes in previous character sets (that is, character sets for which byte 3 has a lower value). The ordering between the sets (byte 3 ) has no meaning beyond dealing with duplicate coding.

As far as possible, KEYSYM values (byte 4) follow the character set encoding standards, except for the Greek and Cyrillic KEYSYMs which are based on early draft standards. In the Latin- 1 to Latin-4 sets, all duplicate glyphs occupy the same code position. However, duplicates between Greek and Technical do not occupy the same code position. ${ }^{9}$
The 94 and 96 -character code sets occupy the right-hand quadrant (decimal 129 through 256), so the ASCII subset has a unique encoding across byte 4 , which corresponds to the ASCII character code. However, this does not apply to all values in the Keyboard set (byte $3=255$ ).
The Keyboard set (byte $3=255$ ) is a collection of commonly occurring keys on keyboards. Within this set, the keypad symbols are generally duplicates of symbols found on keys on the main part of the keyboard, but they are distinguished here because they often have distinguishable semantics associated with them.
This specification captures keys from a variety of keyboards, folding likely aliases into the same KEYSYM (for example, merging Del, DEL, and Delete into a single KEYSYM), rather than creating a KEYSYM for every unique key. ${ }^{10}$
In the tables below, Code Position is a restatement of byte 4 of the KEYSYM value as most-significant/least-significant 4-bit values.
In all cases, the KEYSYM value is:

$$
\text { byte } 3 * 256+\text { byte } 4
$$

[^6]| $\begin{gathered} \text { Byte } \\ 3 \end{gathered}$ | $\begin{array}{\|c\|} \hline \text { Byte } \\ 4 \end{array}$ | Code Position | Name | Set |

## access control list

A list, maintained by a server, of hosts from which clients are authorized to connect to the server.
active grab
A grab is active when the pointer or keyboard is actually owned by the single grabbing client.

## ancestor

An ancestor of a given window is a window above it in the hierarchy.
atom
An atom is a unique ID corresponding to a string name. Atoms are used to identify properties, types, and selections.
background
A solid color or a pixmap that is used to paint portions of an InputOutput window that were lost or invalidated.

## backing store

When a server maintains the contents of a window, the pixels saved off screen are known as a backing store.

## base font name

A font name that selects a family of fonts whose members may use various character encodings. See the XLFD specification (included in the X Window System (X11R6): Fonts and Text Technical Standard).
bit gravity
The affinity of a window's contents for a specified side or corner of the window in cases where the window's size changes.
bit plane
When a pixmap or window is thought of as a stack of bitmaps, each bitmap is called a bit plane or plane.
bitmap
A pixmap of depth one.
border
An undrawable frame surrounding an InputOutput window. The server automatically maintains the contents of the border. Exposure events are never generated for border regions.
button grab
Buttons on the pointer may be passively grabbed by a client. When the button is pressed, the pointer is then actively grabbed by the client.
byte order
The sequence in which a stream of bytes is interpreted (such as big-endian or little-endian).
byte swapping
The process of reordering bytes in a stream of bytes when a client and server have different byte order.

## character

A sequence of one or more bytes representing a single graphic symbol or control code. A character is not bound to a coded value until it is identified as part of a coded character set.

## character glyph

The abstract graphical symbol for a character. Character glyphs might not map one-to-one to font glyphs, and may be context-dependent, varying with the adjacent characters. Multiple characters may map to a single character glyph.

## character set

A finite set of different characters used for the representation, organization, or control of data.

## charset

An encoding with a uniform, state-independent mapping from characters to codepoints (a coded character set).

There can be a direct mapping from a charset to one font, if the width of all characters in the charset is either one or two bytes. A text string encoded in an encoding such as Shift-JIS cannot be passed directly to the server, because the text imaging requests accept only single-width charsets (either 8 or 16 bits). Charsets which meet these restrictions can serve as font charsets. Font charsets map font indices to font glyphs, not characters to character glyphs.
A single font charset is sometimes used as the encoding of a locale; for example, ISO 8859-1.

## children

A window's first-level subwindows.

## client

An application program connected to a server.

## clip region

The area that is painted with the window background when the window is cleared, which contains all graphics output to the window and clips any subwindows.

## coded character

A character bound to a codepoint.

## coded character set

A set of unambiguous rules that establishes a character set and the one-to-one relationship between each character of the set and its bit representation.

## codepoint

The coded representation of a single character in a coded character set.
colormap
A set of entries that map pixel values to colors on the screen.
connection
The path between a server and a client. A client program typically (but not necessarily) has one connection to the server over which requests and events are sent.
contain, containment
A window "contains" the pointer if the window is viewable and the hotspot of the cursor is within a visible region of the window or a visible region of one of its inferiors. The border of the window is included as part of the window for containment. The pointer is "in" a window if the window contains the pointer but no inferior contains the pointer.

## coordinate system

A two-dimensional space with the origin [0, 0] at the upper-left and $Y$ increasing downward. Coordinates are integral, in terms of pixels, and coincide with pixel centers. Each window and pixmap has its own coordinate system. For a window, the origin is inside the border.

## cursor

An instance of a pointer; in a text widget, a rendition that indicates where the next glyph will be drawn.

## depth

The depth of a window or pixmap is the number of valid bit-planes used to represent a pixel.

## device

Keyboards, mice, tablets, track-balls, button boxes, and so on, are all collectively known as input devices. The core $X$ protocol only deals with two devices, the keyboard and the pointing device.

## DirectColor

A visual class in which a pixel value is decomposed into three separate subfields for indexing. The first subfield indexes an array to produce red intensity values. The second subfield indexes a second array to produce blue intensity values. The third subfield indexes a third array to produce green intensity values. The RGB values can be changed dynamically.

## display

A server, together with its screens and input devices.

## drawable

Windows and pixmaps that can be used as sources and destinations in graphics operations. An InputOnly window cannot be used as a source or destination in a graphics operation.

## encoding

A set of unambiguous rules that establishes a character set and a relationship between the characters and their representations. The character set does not have to be fixed to a finite predefined set of characters. The representations do not have to be of uniform length.

## escapement

In a string, the distance in pixels in the primary draw direction from the drawing origin to the origin of the next glyph to be drawn.

## event

Clients are informed of information asynchronously by means of events. These events can be generated either asynchronously from devices or as side effects of client requests.

## event mask

The set of event types that a client requests relative to a window.

## event propagation

The process by which device-related events propagate from the source window to ancestor windows until some client has expressed interest in handling that type of event or until the event is discarded explicitly.

## event source

The window on which an event is generated.

## exposure event

Events sent to clients to inform them that contents of regions of windows need to be redrawn.

## extension

A feature that extends the core X protocol.

## focus window

See input focus on page 191.

## font

A set of glyphs (typically characters), with additional metric information to determine interglyph and interline spacing.

## gamut

The color gamut of a device is the full range of colors that can be produced by the device.

## GC, GContext

See graphics context.

## glyph

A glyph is an image, typically of a character, in a font.

## glyph image

An image of a glyph, as obtained from a glyph representation displayed on a presentation surface.

## grab

Keyboard keys, the keyboard, pointer buttons, the pointer, and the server can be grabbed for exclusive use by a client. In general, these facilities are not intended to be used by normal applications but are intended for various input and window managers to implement various styles of user interface.

## graphics context

Various information for graphics output such as foreground pixel, background pixel, line width, clipping region, and so on. A graphics context can only be used with drawables that have the same root and the same depth as the graphics context.

## gravity

See bit gravity on page 187 and window gravity on page 196.

## GrayScale

A degenerate case of PseudoColor, in which the red, green, and blue values in any given colormap entry are equal, thus producing shades of gray. The gray values can be changed dynamically.

## Host Portable Character Encoding

The encoding of the $X$ Portable Character Set on the host. The encoding must be the same in all locales supported by the server. If a string is said to be in the Host Portable Character Encoding, then it only contains characters from the X Portable Character Set, in the host encoding.

## hotspot

The point in the cursor corresponding to the coordinates reported for the pointer.

## identifier

A unique value associated with a resource that clients use to name that resource. The identifier can be used over any connection.

## image

A client-side object that represents a rectangular graphic.

## inferior

The inferiors of a window are all of the subwindows nested below it in the hierarchy: the children, the children's children, and so on. The term descendant is a synonym.

## input focus

The input focus is normally a window defining the scope for processing of keyboard input. If a generated keyboard event would normally be reported to this window or one of its inferiors, the event is reported normally. Otherwise, the event is reported with respect to the focus window. The input focus also can be set such that all keyboard events are discarded and such that the focus window is dynamically taken to be the root window of whatever screen the pointer is on at each keyboard event.

## input manager

Control over keyboard input is typically provided by an input manager client.

## InputOnly window

A window that cannot be used for graphics requests. InputOnly windows are invisible and can be used to control such things as cursors, input event generation, and grabbing. InputOnly windows cannot have InputOutput windows as inferiors.

## InputOutput window

An opaque window used for both input and output. InputOutput windows can have both InputOutput and InputOnly windows as inferiors.

## internationalization

The process of making software adaptable to the requirements of different native languages, local customs, and character string encodings. Making a computer program adaptable to different locales without program source modifications or recompilation.

ISO 2022
ISO standard for code extension techniques for 7-bit and 8-bit coded character sets.
key grab
Keys on the keyboard can be passively grabbed by a client. When the key is pressed, the keyboard is then actively grabbed by the client.

## keyboard grab

A client can actively grab control of the keyboard, and key events are sent to that client rather than to the client the events would normally have been sent to.
keysym
An encoding of a symbol on a keycap on a keyboard.

## Latin-1

The coded character set defined by the ISO 8859-1 standard.

## Latin Portable Character Encoding

The encoding of the X Portable Character Set using the Latin-1 codepoints plus ASCII control characters. If a string is said to be in the Latin Portable Character Encoding, then it only contains characters from the X Portable Character Set, not all of Latin-1.
locale
The definition of the subset of a user's environment that depends on language and cultural convention. In this Technical Standard, the current locale is the current setting of the LC_CTYPE setlocale category. The current locale affects:

- Encoding and processing of input method text
- Encoding of resource files and values
- Encoding and imaging of text strings
- Encoding and decoding for inter-client text communication

## localization

The process of establishing information within a computer system specific to the operation of particular native languages, local customs, and coded character sets.

## mapped

A window is said to be mapped if a map call has been performed on it. Unmapped windows and their inferiors are never viewable or visible.

## modifier keys

Shift, Control, Meta, Super, Hyper, Alt, Compose, Apple, CapsLock, ShiftLock, and similar keys are called modifier keys.

## monochrome

A special case of StaticGray in which there are only two colormap entries.

## multibyte character

A sequence of one or more bytes representing a single graphic symbol or control code. This term corresponds to the same term in the ISO C standard, where a single-byte character is a special case of a multi-byte character. Unlike the usage in the ISO C standard, character here has no necessary relationship with storage space, and byte is used when storage space is discussed.

## obscure

Window A obscures window B if both are viewable InputOutput windows, A is higher in the global stacking order, and the rectangle defined by the outside edges of $A$ intersects the rectangle defined by the outside edges of $B$. Window borders are included in the calculation. A window can be obscured and yet still have visible regions. (See occlude.)

## occlude

Window A occludes window B if both are mapped, A is higher in the global stacking order, and the rectangle defined by the outside edges of $A$ intersects the rectangle defined by the outside edges of B. Window borders are included in the calculation. (See obscure.)

## padding

Bytes inserted in the data stream to maintain alignment of the protocol requests on natural boundaries. This increases ease of portability to some machine architectures.

## parent window

If $C$ is a child of $P$, then $P$ is the parent of $C$.
passive grab
Grabbing a key or button is a passive grab. The grab activates when the key or button is actually pressed.

## pixel value

An N-bit value, where N is the number of bit planes used in a particular window or pixmap (that is, N is the depth of the window or pixmap). For a window, a pixel value indexes a colormap to derive an actual color to be displayed.

## pixmap

Off-screen resources that are used for various operations, such as defining cursors as tiling patterns or as the source for certain raster operations. A pixmap is a three-dimensional array
of bits, normally thought of as a two-dimensional array of pixels, where each pixel can be a value from 0 to $\left(2^{\mathrm{N}}\right)-1$ and where N is the depth ( Z axis) of the pixmap. A pixmap can also be thought of as a stack of N bitmaps.

## plane

When a pixmap or window is thought of as a stack of bitmaps, each bitmap is called a plane or bit plane.
plane mask
A bit mask describing which planes are to be modified by graphics operations.

## pointer

The graphical representation indicating the location of the pointing device.
pointer grab
A client can actively grab control of the pointer. Button and motion events are then sent to that client rather than to the client to which the events would normally have been sent.

## pointing device

A pointing device is typically a mouse, tablet, or some other device with effective dimensional motion. There is only one visible cursor defined by the core protocol, and it tracks whatever pointing device is attached as the pointer.

## POSIX

Portable Operating System Interface, ISO/IEC 9945-1 (IEEE Std. 1003.1).

## POSIX Portable Filename Character Set

The set of 65 characters which can be used in naming files on a POSIX-compliant host that are correctly processed in all locales. The set is:
a..z A..Z 0.. 9 ._-

## property

Windows may have associated properties, which consist of a name, a type, a data format, and some data. The protocol places no interpretation on properties. They are intended as a general-purpose naming mechanism for clients. For example, clients might use properties to share information such as resize hints, program names, and icon formats with a window manager.
property list
The list of properties that have been defined for a window.

## PseudoColor

A class of colormap in which a pixel value indexes the colormap to produce independent red, green, and blue values. That is, the colormap is viewed as an array of triples (RGB values). The RGB values can be changed dynamically.
redirecting control
Window managers (or client programs) may want to enforce window layout policy in various ways. When a client attempts to change the size or position of a window, the operation may be redirected to a specified client rather than the operation actually being performed.
renderer
Code that takes font data in its raw format and converts it to the font server's format.
reply
Information requested by a client is sent back to the client with a reply. Both events and replies are multiplexed on the same connection. Most requests do not generate replies,
although some requests generate multiple replies.

## request

A command to the server; a single block of data sent over a connection.

## resource

Windows, pixmaps, cursors, fonts, graphics contexts, and colormaps are known as resources. All have unique identifiers associated with them for naming purposes. The lifetime of a resource usually is bounded by the lifetime of the connection over which the resource was created.

## RGB values

Red, green, and blue (RGB) intensity values are used to define color. These values are always represented as 16 -bit unsigned numbers, with 0 being the minimum intensity and 65535 being the maximum intensity. The server scales the values to match the display hardware.

## root window

The common ancestor of all windows for a screen. A root window has no parent.
save-set
A client's list of other clients' windows that, if they are inferiors of one of the client's windows at connection close, should not be destroyed and should be remapped if currently unmapped. Save sets are typically used by window managers to avoid lost windows if the manager terminates abnormally.

## scanline

A list of pixel or bit values viewed as a horizontal row (all values having the same y coordinate) of an image, with the values ordered by increasing $X$ coordinate.

## scanline order

Scanlines ordered by increasing Y coordinate.
screen
A bounded displayable area that houses the root window. A server can provide several independent screens, which typically have physically independent monitors.

## selection

A selection can be thought of as an indirect property with dynamic type; that is, rather than having the property stored in the server, it is maintained by some client (the "owner"). A selection is global in nature and is thought of as belonging to the user (although maintained by clients), rather than as being private to a particular window subhierarchy or a particular set of clients. When a client asks for the contents of a selection, it specifies a selection "target type". This target type can be used to control the transmitted representation of the contents. For example, if the selection is "the last thing the user clicked on" and that is currently an image, then the target type might specify whether the contents of the image should be sent in XY format or Z format. The target type can also be used to control the class of contents transmitted; for example, asking for the "looks" (fonts, line spacing, indentation, and so on) of a paragraph selection rather than the text of the paragraph. The target type can also be used for other purposes, but such semantics are unspecified.

## server

The server provides the basic windowing mechanism. It handles connections from clients, multiplexes graphics requests onto the screens, and demultiplexes input back to the appropriate clients.

## server grab

The server can be grabbed by a single client for exclusive use. This prevents processing of any requests from other client connections until the grab is completed. This is typically only a transient state for such things as rubber-banding, pop-up menus, or to execute requests indivisibly.

## shift sequence

Control characters and escape sequences which temporarily (single shift) or permanently (locking shift) cause a different character set to be in effect ("invoking" a character set).

## sibling

A child of the same parent window.

## stacking order

The relationship between sibling windows that determines whether some windows obscure or occlude others.

## state-dependent encoding

An encoding in which an invocation of a charset can apply to multiple characters in sequence. A state-dependent encoding begins in an "initial state" and enters other "shift states" when specific "shift sequences" are encountered in the byte sequence.

## state-independent encoding

Any encoding in which the invocations of the charsets are fixed, or span only a single character.

## StaticColor

A degenerate case of PseudoColor in which the RGB values are predefined and read-only.

## StaticGray

A degenerate case of GrayScale in which the gray values are predefined and read-only. The values are typically linear or near-linear increasing ramps.

## status

The return value of many functions.

## stipple

A bitmap used to tile a region that may also serve as an additional clip mask for a fill operation with the foreground color.

## tile

A pixmap can be replicated in two dimensions to tile a region. The pixmap itself is also known as a tile.

## timestamp

A time value expressed in milliseconds. It typically is the time since the last server reset. Timestamp values wrap around (after about 49.7 days).

## top-level

A child of the root window.

## TrueColor

A degenerate case of DirectColor in which the subfields in the pixel value directly encode the corresponding RGB values; that is, the colormap has predefined read-only RGB values. The values are typically linear or near-linear increasing ramps.
type
An arbitrary atom used to identify the interpretation of property data. Types are completely uninterpreted by the server and are solely for the benefit of clients.

## unviewable

A window is unviewable if it is mapped but some ancestor is unmapped. See also viewable.

## viewable

A window is viewable if it and all of its ancestors are mapped. This does not imply that any portion of the window is actually visible. Graphics requests can be performed on a window when it is not viewable, but output is not retained unless the server is maintaining backing store.

## visible

A region of a window is visible if someone looking at the screen can actually see it; that is, the window is viewable and the region is not occluded by any other window.
whitespace
Any spacing character. On implementations that conform to the ISO C library, whitespace is any character for which the isspace ( ) function returns true.

## window

An area (usually rectangular) on the screen that holds graphical output.

## window gravity

When windows are resized, subwindows may be repositioned automatically relative to some position in the window. This attraction of a subwindow to some part of its parent is known as window gravity.

## window manager

A client that manipulates windows on the screen and typically provides the user interface policy.

## X Portable Character Set

A basic set of 97 characters which are assumed to exist in all locales supported by this Technical Standard. This set contains the following characters:

$$
\text { a..z A..Z } 0 . .9 \text { !"\#\$\%\&'( })^{*}+,-. /: ;<=>@[\backslash]^{\wedge} \_\{\mid\}^{\sim}<\text { space>, <tab>, and <newline> }
$$

This is the left/lower half (also called the G0 set) of the graphic character set of ISO 8859-1 plus <space>, <tab>, and <newline>. It is also the set of graphic characters in 7-bit ASCII plus the same three control characters. The actual encoding of these characters on the host is implementation-dependent; see Host Portable Character Encoding on page 190.

## XDCCC

The $X$ Device Color Characterization Convention, a method of specifying deviceindependent color spaces.

## XLFD

The $X$ Logical Font Description Conventions that define a standard syntax for structured font names.

## XY Format

The data for a pixmap is said to be in $X Y$ format if it is organized as a set of bitmaps representing individual bit planes, with the planes appearing from most-significant to least-significant in bit order.

## Z Format

The data for a pixmap is said to be in Z format if it is organized as a set of pixel values in scanline order.

[^0]:    1. Application Usage: This corresponds to the JIS/ISO method of indexing 2-byte characters.
[^1]:    2. Application Usage: To obtain more accurate information on the colormap and visual capabilities of advanced graphics hardware, applications should use the Extended Visual Information (EVI) Extension.
[^2]:    5. Application Usage: If the server maintains contents, then it should maintain complete contents, not just the region within the parent boundaries, even if the window is larger than its parent. While the server maintains contents, exposure events are not normally generated, but the server may stop maintaining contents at any time.
[^3]:    6. Application Usage: Freeing an individual pixel obtained from AllocColorPlanes may not actually let it be reused until all related pixels are freed. Similarly, a read-only entry is not actually freed until it has been freed by all clients, and if a client allocates the same read-only entry multiple times, it must free the entry that many times before the entry is actually freed.
[^4]:    * Application Usage: Must be set to 0 .

[^5]:    $\dagger$ See Section 5.6 on page 147.

[^6]:    * This appendix does not define any new keysyms for these character sets. All keysyms in these character sets are reserved.

    9. Application Usage: Applications that use the Latin-2, Latin-3, Latin-4, Greek, Cyrillic, or Technical sets may find it convenient to use arrays to transform the KEYSYMs.
    10. Application Usage: For example, providing a single, keyboard-independent KEYSYM for Delete lets an application implement a deletion function and expect reasonable bindings on a wide set of workstations.
